Chapter 5:

Elasticity and Its Application

2021/10/8	Elasticity	Joseph Tao-yi Wang

In This Chapter

‣ What is elasticity?

‣ What kinds of issues can elasticity help us understand?

‣ What is the price elasticity of demand?

   ‣ How is it related to the demand curve?

   ‣ How is it related to revenue and expenditure?

‣ What is the price elasticity of supply?

   ‣ How is it related to the supply curve?

‣ What are income and cross-price elasticities of demand?

2021/10/8	Elasticity	Joseph Tao-yi Wang

Our Scenario

▸ You maintain the social media accounts for local businesses

  ▸ You charge NT$6,000 per business, and currently maintain the social media accounts for 12 businesses per year.

▸ Your costs are rising (including the opportunity cost of your time).

  ▸ You consider raising the price to NT$7,500.

Our Scenario

▸ The law of demand: if you raise your price, you will not have as many accounts to maintain.

  ▸ How many fewer accounts?

 ▸ How much will your revenue fall, or might it increase?

The Elasticity of Demand

▸ Elasticity
  ▸ Measure of the responsiveness of Q^d or Q^s to a change in one of its determinants
▸ Price Elasticity of Demand
  ▸ How much the quantity demanded of a good responds to a change in the price of that good
    ▸ Loosely speaking, it measures the price-sensitivity of buyers' demand
  ▸ Actually, price elasticity IS price sensitivity!

The Price Elasticity of Demand

P rises by 10%

Q falls by 15%
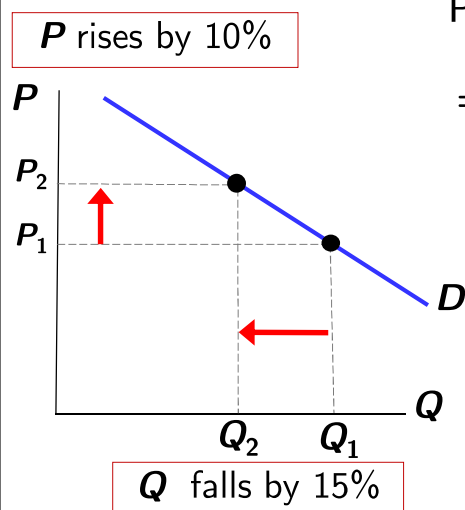

Price Elasticity of Demand is

$$= \frac{\text{Percentage change in } Q^d}{\text{Percentage change in } P} = \frac{15\%}{10\%} = 1.5$$

Along a D curve, P and Q move in opposite directions, which would make **price elasticity negative**.

We will drop the minus sign and report all price elasticities as positive numbers (absolute values).

Calculating Percentage Changes

Demand for maintaining social media accounts

P

B
$7500 ----
$6000 ----   A

D
8 12 Q

‣ Going from B to A:
  ‣ % change in P = -20%
  ‣ % change in Q = 50%
‣ Price elasticity = 50/20 = **2.5**

Standard method of computing the percentage (%) change:

$$\frac{\text{end value} - \text{start value}}{\text{start value}} \times 100\%$$

‣ Going from A to B:
  ‣ the % change in P = 25%
  ‣ the % change in Q = -33%
‣ Price elasticity = 33/25 = **1.33**

We get different values!

The Price Elasticity of Demand

‣ Midpoint method
  ‣ The midpoint is the number halfway between the start and end values
    ‣ The average of those values
 ‣ % change = $\frac{\text{end value} - \text{start value}}{\text{midpoint}} \times 100\%$

  ‣ Price elasticity of demand = $\dfrac{\frac{Q_2 - Q_1}{(Q_2 + Q_1)/2}}{\frac{P_2 - P_1}{(P_2 + P_1)/2}}$

Our Scenario: Calculating Percentage Changes

Demand for maintaining
social media accounts

Using the midpoint method of
computing % changes:

% change in $P =$

$$\frac{\$7{,}500 - \$6{,}000}{\$6{,}750} \times 100\%$$

$$= \boxed{22.2\%}$$

% change in $Q = \dfrac{12 - 8}{10} \times 100\% = \boxed{40.0\%}$

Price elasticity of demand $= 40/22.2 = \boxed{1.8}$

Active Learning 1: Answers

Using the midpoint method to calculate percentage changes:

A. % change in P =

[($50,400 - $32,900)/$41,650] ×100 = 42.02%

B. % change in Q^d =

[(10,600 − 8,400)/9,500] ×100 = 23.16%

C. Price elasticity of demand =

= % change in Q^d / % change in P

= 23.16/42.02 = 0.55

Determinants of Price Elasticity of Demand

We look at a series of examples comparing two common goods.

▸ In each example:

  ▸ Suppose prices of both goods rise by 20%

  ▸ Which good has the highest price elasticity of demand? Why?

  ▸ What lesson we learn about the determinants of price elasticity of demand?

Example 1: Samsung S21 vs. iPhone 13 Pro

▸ Prices of both of these goods rise by 20%.
For which good does Q^d drop the most? Why?

▸ Samsung S21 has many close substitutes, so buyers can easily switch if the price rises

▸ iPhone 13 Pro has no close substitutes, so a price increase would not affect demand much

▸ Price elasticity is higher when close substitutes are available.

Example 2: Mountain Dew vs. Soda (Pop)

▸ Prices of both of these goods rise by 20%.
  For which good does Q^d drop the most? Why?

▸ For a narrowly defined good, Mountain Dew, there are many substitutes

▸ There are fewer substitutes available for broadly defined goods (soda / pop)

▸ Price elasticity is higher for narrowly defined goods than for broadly defined ones.

Example 3: Insulin vs. Rolex Watches

▸ Prices of both of these goods rise by 20%.
For which good does Q^d drop the most? Why?

▸ Insulin is a necessity to diabetics. A rise in price would cause little or no decrease in quantity demanded

▸ A Rolex watch is a luxury. If the price rises, some people will forego it.

▸ Price elasticity is higher for luxuries than for necessities.

Example 4: Gasoline, Short Run vs. Long Run

- The price of gasoline rises 20%. Does Q^d drop more in the short run or the long run? Why?
- There's not much people can do in the short run, other than ride the bus or carpool.
- In the long run, people can buy smaller cars or live closer to work.
- Price elasticity is higher in the long run.

Elasticity Along a Linear Demand Curve

$E = \dfrac{200\%}{40\%} = 5.0$

$E = \dfrac{67\%}{67\%} = 1.0$

Our Scenario: Total Revenue

Continuing our scenario, if you raise your price from $6,000 to $7,500, would your revenue rise or fall?

Total Revenue $(TR) = P \times Q$

▸ A price increase has two effects on revenue:
  ▸ Higher revenue: because of the higher P
  ▸ Lower revenue: you maintain fewer accounts (lower Q)
▸ Which of these two effects is bigger?
 ▸ It depends on the price elasticity of demand

‣ When **D** is inelastic, a price increase causes revenue to rise.

Price Elasticity and Total Revenue

‣ For a price increase, if demand is elastic
  ‣ **E** > 1: % change in **Q** > % change in **P**

  ‣ **TR** increases: the fall in revenue from lower **Q** < the increase in revenue from higher **P**

Active Learning 2: Answers, A

A. Pharmacies raise the price of insulin by 10%.

‣ Does total expenditure on insulin rise or fall?

‣ Expenditure = total revenue = $P \times Q$
‣ Since demand for insulin is inelastic, Q will fall less than 10%, so expenditure rises.

B. As a result of a fare war, the price of a luxury cruise falls 20%.

▸ Does luxury cruise companies' total revenue rises or falls?

▸ Revenue = $P \times Q$

▸ The fall in P reduces revenue, but Q increases, which increases revenue. Which effect is bigger?

▸ Since demand is elastic, Q will increase more than 20%, so revenue rises.

Chapter in a Nutshell

▸ The price elasticity of demand

  ▸ Measures how much the quantity demanded responds to changes in the price.

  ▸ Is the percentage change in quantity demanded divided by the percentage change in price.

▸ If < 1, inelastic demand: quantity demanded moves proportionately less than the price

▸ If > 1, elastic demand: quantity demanded moves proportionately more than the price

Chapter in a Nutshell

▸ Demand tends to be more elastic if

  ▸ Close substitutes are available

  ▸ The good is a luxury rather than a necessity

  ▸ The market is narrowly defined

  ▸ If buyers have substantial time to react to a price change.

▸ Total revenue ($P \times Q$), total amount paid for a good

  ▸ Moves in the same direction as P (inelastic D)

  ▸ Moves in the opposite direction as P (elastic D)

Chapter in a Nutshell

- The income elasticity of demand
  - Measures how much the quantity demanded responds to changes in consumers' income
- The cross-price elasticity of demand
  - Measures how much the quantity demanded of one good responds to changes in the price of another good
    - The tools of supply and demand can be applied to many different kinds of markets. This chapter uses them to analyze the market for wheat, for oil, and for illegal drugs.

Chapter in a Nutshell

- The price elasticity of supply
  - Measures how much the quantity supplied responds to changes in the price.
  - Is the percentage change in quantity supplied divided by the percentage change in price
  - If < 1, inelastic supply: quantity supplied moves proportionately less than the price
  - If > 1, elastic supply: quantity supplied moves proportionately more than the price
    - Depends on the time horizon under consideration. In most markets, supply is more elastic in the long run than in the short run.
