

1. Define " $K$  is a *compact set* in the metric space  $X$ ".

A set in  $K$  is compact in  $X$  if every open cover of  $K$  has a finite subcover.

#

2. Is the set  $S$  compact in  $X$ ?

- (i)  $X = \mathbb{R}^2$ .  $S$  is some open ball  $N_r(x)$  for  $r > 0$ .
- (ii)  $S$  is an empty set.
- (iii)  $X = \mathbb{R}^5$ .  $S$  is a non-empty finite set.

(i) No. Consider an increasing sequence  $\{r_n\}_{n \geq 1}$ ,  $r_n = \frac{n}{n+1}r$ , and  $r_n \rightarrow r$ . Then  $\bigcup_{n \geq 1} N_{r_n}(x)$  is an open cover of  $N_r(x)$  but does not have a finite subcover.

(ii) Yes.

(iii) Yes. Every finite set is compact.

3. Given  $X$  being a metric space and  $K \subset Y \subset X$ . Prove that  $K$  is compact in  $Y$  if and only if  $K$  is compact in  $X$ .

( $\Rightarrow$ ): Suppose  $K$  is compact in  $Y$ . If  $\{U_\alpha\}$  is an open covers of  $K$  in  $X$ , let  $V_\alpha = U_\alpha \cap Y$ , then  $\{V_\alpha\}$  is an open cover of  $K$  in  $Y$ . Since  $K$  is compact in  $Y$ ,  $\exists$  a finite subcover  $V_{\alpha_1} \cup \dots \cup V_{\alpha_n}$  in  $Y$ .  $\Rightarrow U_{\alpha_1} \cup \dots \cup U_{\alpha_n}$  is a finite subcover of  $K$  in  $X$ .

( $\Leftarrow$ ): Suppose  $K$  is compact in  $X$ . If  $\{V_\alpha\}$  is an open cover of  $K$  in  $Y$ , since  $V_\alpha$  is relative open in  $Y$ ,  $\exists U_\alpha$  open in  $X$  s.t.  $V_\alpha = Y \cap U_\alpha$ .

We have  $\{U_\alpha\}$  is an open cover of  $K$  in  $X$ , so

$\exists$  a finite subcover  $U_{\alpha_1} \cup \dots \cup U_{\alpha_n}$  of  $K$  in  $X$

$\Rightarrow V_{\alpha_1} \cup \dots \cup V_{\alpha_n}$  is a finite subcover of  $K$  in  $Y$ .  $\#$

4. Let  $F$  be a closed set and  $K$  be a compact set. Prove that  $F \cap K$  is a compact set.

$K$  is compact  $\Rightarrow K$  is closed  $\Rightarrow F \cap K$  is a closed  
subset in compact set  $K \Rightarrow F \cap K$  is compact. #

5. Let  $K = \{0\} \cup \left\{ \frac{1}{n} \mid n \in \mathbb{N} \right\}$ . Prove that  $K$  is compact (without using Heine-Borel if you know what it is).

Let  $\{U_\alpha\}$  be any open cover of  $K$ , then  $\exists G \in \{U_\alpha\}$  s.t.

$0 \in G$ . Hence  $\exists$  sufficient large  $m$  s.t.  $N_{\frac{1}{m}}(0) \subseteq G$ .

Let  $G_n$  be a set s.t.  $G_n \in \{U_\alpha\}$  and  $\frac{1}{n} \in G_n$ .

$\Rightarrow G, G_1, \dots, G_{m-1}$  is a finite subcover of  $K$

$\Rightarrow K$  is compact.
