ABSTRACT: Two novel poly(amine-hydrazide)s were prepared from the polycondensation reactions of the dicarboxylic acid, 9-[N,N-di(4-carboxyphenyl)amino]anthracene (1), with terephthalic dihydrazide (TPH) and isophthalic dihydrazide (IPH) via the Yamazaki phosphorylation reaction, respectively. The poly(amine-hydrazide)s were readily soluble in many common organic solvents and could be solution cast into transparent films. Differential scanning calorimetry (DSC) indicated that these hydrazide polymers had glass-transition temperatures \(T_g\) in the range of 182–230 °C and could be thermally cyclodehydrated into the corresponding oxadiazole polymers in the range of 300–400 °C. The resulting poly(amine-1,3,4-oxadiazole)s had useful levels of thermal stability associated with high \(T_g\) (263–318 °C), 10% weight-loss temperatures in excess of 500 °C, and char yield at 800 °C in nitrogen higher than 55%. These organo-soluble anthrylamine-based poly(amine-hydrazide)s and poly(amine-1,3,4-oxadiazole)s exhibited maximum UV-vis absorption at 346–349 and 379–388 nm in N-methyl-2-pyrrolidone (NMP) solution, respectively. Their photoluminescence spectra in NMP solution showed maximum bands around 490–497 nm in the green region. The poly(amine-hydrazide) I-IPH showed a green photoluminescence at 490 nm with PL quantum yield of 29.9% and 17.0% in NMP solution and film state, respectively. The anthrylamine-based poly(amine-1,3,4-oxadiazole)s revealed a electrochromic characteristics with changing color from the pale yellow neutral form to the red reduced form when scanning potentials negatively from 0.00 to −2.20 V. © 2009 Wiley Periodicals, Inc. INTRODUCTION

Electrochromism is known as the reversible change of the color resulting from the oxidation or the reduction of the material by electrochemical means. Color changes are commonly between a transparent state, where the chromophore only absorbs in the UV region, and a colored state or between two colored states in a given electrolyte solution. This interesting property led to the development of many technological applications such as automatic antiglazing mirror,1 smart windows,2 electrochromic displays,3 and chameleon materials.4 Triarylamine-containing polymers5 are not only widely used as the electrochromic materials,6
but also have attracted considerable interest as photoluminescent materials.\textsuperscript{7} Oxadiazole derivatives are often associated with luminescent polymers as an electron transporting molecules either in the same layer or bilayer system. Aromatic poly(1,3,4-oxadiazole)s are a class of chemically resistant and thermally stable heterocyclic polymers.\textsuperscript{8} Recently, 1,3,4-oxadiazole-containing conjugated polymers have been widely investigated and applied as electron transport or emission layers in polymer light-emitting diodes (LEDs).\textsuperscript{9} The primary reason for this use is the high photoluminescent quantum yield in the visible region that characterizes many of these materials, combined with the advantage of simple processability into flexible, mechanically robust films or thin layers. Unfortunately, aromatic polyoxadiazoles are difficult to process owing to their infusible and insoluble properties and their tendency to be brittle. To overcome these limitations, polymer-structure modification becomes necessary. Recently, we have reported the synthesis of soluble aromatic polyimides and polyamides bearing triphenylamine units in the main chain.\textsuperscript{10} Because of the incorporation of bulky, propeller-shaped triphenylamine units along the polymer backbone, all the polymers were amorphous with high thermal stability, showed good solubility in many organic solvents, and good film-forming capability.

In this article, we therefore synthesized the novel poly(amine-hydrazide)s and poly(amine-1,3,4-oxadiazole)s derived from anthrylamine-based dicarboxylic acid monomer, 9-[N,N-di(4-carboxyphenyl)amino]anthracene\textsuperscript{11} (1) (mp: 338–339 °C), 1-[N,N-di(4-carboxyphenyl)amino]naphthalene\textsuperscript{12} (2) (mp: 316–318 °C), and 4,4’-dicarboxytriphenylamine\textsuperscript{13} (3) (mp: 313–315 °C) were synthesized according to the previously reported procedures. Terephthalic dihydrazide (TPH) and isophthalic dihydrazide (IPH) were purchased from Tokyo Chemical Industry Co., Ltd. (TCI) and used without further purification. Commercially available anhydrous calcium chloride (CaCl\textsubscript{2}) was dried under vacuum at 180 °C for 8 h. Tetrabutylammonium perchlorate (TBAP) (Acros) was recrystallized twice from ethyl acetate and then dried in vacuo before use. All other reagents were used as received from commercial sources.

Polymer Synthesis

General Polymer Synthesis

The new poly(amine-hydrazide)s were synthesized from dicarboxylic acid monomer I and dihydrazides via phosphorylation polycondensation method, respectively. A typical synthetic procedure for poly(amine-hydrazide) I-TPH is described as follows. A dried 25-mL flask was charged with 1 (0.217 g; 0.5 mmol), TPH (0.097 g; 0.5 mmol), NMP (0.5 mL), calcium chloride (0.06 g), diphenyl phosphate (0.5 mL), and pyridine (0.25 mL). The mixture was heated with stirring at 120 °C for 5 h. As polycondensation proceeded, the solution became viscous gradually. The resulting highly viscous polymer solution was poured slowly into 300 mL of methanol with stirring, giving a fibrous precipitate that was collected by filtration, washed thoroughly with hot water and methanol. Precipitations from N,N-dimethylacetamide (DMAc) into methanol were carried out twice for further purification. The yield as quantitative, and the inherent viscosity and weight-average molecular weights (\(M_w\)) of the obtained poly(amine-hydrazide) I-TPH was 0.39 dL/g (measured at a concentration of 0.5 g/dL in DMAc at 30 °C) and 23,100 Da, respectively.

EXPERIMENTAL

Materials

9-[N,N-di(4-carboxyphenyl)amino]anthracene\textsuperscript{11} (1) (mp: 338–339 °C), 1-[N,N-di(4-carboxyphenyl)amino]naphthalene\textsuperscript{12} (2) (mp: 316–318 °C), and 4,4’-dicarboxytriphenylamine\textsuperscript{13} (3) (mp: 313–315 °C) were synthesized according to the previously reported procedures. Terephthalic dihydrazide (TPH) and isophthalic dihydrazide (IPH) were purchased from Tokyo Chemical Industry Co., Ltd. (TCI) and used without further purification. Commercially available anhydrous calcium chloride (CaCl\textsubscript{2}) was dried under vacuum at 180 °C for 8 h. Tetrabutylammonium perchlorate (TBAP) (Acros) was recrystallized twice from ethyl acetate and then dried in vacuo before use. All other reagents were used as received from commercial sources.

Polymer Synthesis

General Polymer Synthesis

The new poly(amine-hydrazide)s were synthesized from dicarboxylic acid monomer I and dihydrazides via phosphorylation polycondensation method, respectively. A typical synthetic procedure for poly(amine-hydrazide) I-TPH is described as follows. A dried 25-mL flask was charged with 1 (0.217 g; 0.5 mmol), TPH (0.097 g; 0.5 mmol), NMP (0.5 mL), calcium chloride (0.06 g), diphenyl phosphate (0.5 mL), and pyridine (0.25 mL). The mixture was heated with stirring at 120 °C for 5 h. As polycondensation proceeded, the solution became viscous gradually. The resulting highly viscous polymer solution was poured slowly into 300 mL of methanol with stirring, giving a fibrous precipitate that was collected by filtration, washed thoroughly with hot water and methanol. Precipitations from N,N-dimethylacetamide (DMAc) into methanol were carried out twice for further purification. The yield as quantitative, and the inherent viscosity and weight-average molecular weights (\(M_w\)) of the obtained poly(amine-hydrazide) I-TPH was 0.39 dL/g (measured at a concentration of 0.5 g/dL in DMAc at 30 °C) and 23,100 Da, respectively.
IR (film): 3271 (N–H), 1657 cm⁻¹ (amide carbonyl). The other poly(amine-hydrazide)s were prepared by an analogous procedure.

Film Preparation and Cyclodehydration of the Hydrazide Polymers

A solution of polymer was made by dissolving about 0.3 g of the poly(amine-hydrazide) sample in 5 mL of DMAC, and the homogeneous solution was poured into a 5-cm glass culture dish, which was heated at 50 °C for 1 h, 100 °C for 2 h, and 160 °C for 5 h to slowly release the solvent under vacuum. The obtained film with the thickness of 30–40 µm was used for X-ray diffraction measurements, solubility tests, thermal analyses, optical and electrochemical properties, and electrochemical characteristics measurements.

The cyclodehydration of the poly(amine-hydrazide)s to the corresponding poly(amine-1,3,4-oxadiazole)s were carried out by successive heating the above fabricated polymer films at 200 °C for 30 min, 300 °C for 1 h, and then 350 °C for 3 h under vacuum.

Anal. Calcd of IV-TPH for \((C_{36}H_{21}N_5O_2)_n\) (555.58): C, 77.83%; H, 3.81%; N, 12.61%. Found: C, 75.92%; H, 3.95%; N, 13.01%.

Measurements

Fourier transform infrared (FT-IR) spectra were recorded on a PerkinElmer RXI FT-IR spectrometer. Elemental analyses were run on a VarioEL-III Elementar. The inherent viscosities were determined at 0.5 g/dL concentration using Tamson TV-2000 viscometer at 30 °C. Molecular weight and molecular weight distributions were determined through gel permeation chromatography (GPC) at 50 °C using a Waters 510 HPLC, equipped with a 410 differential refractometer, a refractive index (RI) detector, and an UV detector. Three Ultrastyragel columns (100, 500, and 10^5) were connected in series in order of increasing pore size, with N,N-dimethylformamide (DMF) as eluent at a flow rate of 0.6 mL/min. The molecular weight calibration curve was obtained using polystyrene standards. Wide-angle X-ray diffraction (WAXD) measurements were performed at room temperature (~25 °C) on a Shimadzu XRD-7000 X-ray diffractometer (40 kV, 20 mA), using graphite-monochromatized Cu-Kα radiation. Thermogravimetric analysis (TGA) was conducted with a PerkinElmer Pyris 1 TGA. Experiments were carried out on approximately 6–8 mg film samples heated in flowing nitrogen or air (flow rate: 20 cm³/min) at a heating rate of 20 °C/min. DSC analyses were performed on a PerkinElmer Pyris Diamond DSC at a scan rate of 20 °C/min in flowing nitrogen (flow rate: 20 cm³/min). Ultraviolet-visible (UV-vis) spectra of the polymer films were recorded on a Varian Cary 50 Probe spectrometer. Absorption spectra in spectroelectrochemical analysis were measured with a HP 8453 UV-visible spectrophotometer. Photoluminescence (PL) spectra were measured with a Jasco FP-6300 spectrofluorometer. PL quantum yields \((\Phi_{PL})\) of the samples in NMP were measured by using quinine sulfate dissolved in 1 N sulfuric acid as a reference standard \((\Phi_{PL} = 0.546)^{14}\). The photoluminescence quantum yields of polymer thin films were determined using a calibrated integrating sphere coupled to a charge coupled device (CCD) spectrograph. The 325-nm line of the He-Cd laser was used to excite samples placed in the calibrated integrating sphere. All spectra were obtained by averaging five scans. Differential pulse voltammetry (DPV) and cyclic voltammetry (CV) measurements were carried out with CH Instruments (USA) controlled by an external personal computer. ITO (polymer films area about 0.7 cm × 0.5 cm) was used as a working electrode and a platinum wire as an auxiliary electrode at a scan rate of 50 and 200 mV/s against a Ag/AgCl reference electrode in dry acetonitrile (CH₃CN) and DMF solution of 0.1 M tetrabutylammonium perchlorate (TBAP) under nitrogen atmosphere for oxidation and reduction measurements, respectively. Voltammograms are presented with the positive/negative potential pointing to the right/left with increasing anodic/decreasing cathodic current pointing upward/downward. The spectroelectrochemical cell was composed of a 1 cm cuvette, ITO as a working electrode, a platinum wire as an auxiliary electrode, and a home-made Ag/AgCl, KCl (sat.) reference electrode.

RESULTS AND DISCUSSION

Polymer Synthesis

A two-step procedure was employed to obtain the poly(amine-1,3,4-oxadiazole)s from the dicarboxylic acid monomers with TPH and IPH, respectively, as shown in Scheme 1. The first stage consists of the synthesis of hydrazide prepolymers which are converted to the corresponding oxadiazole polymers in the second stage by the thermal cyclodehydration of the hydrazide group into the

**Journal of Polymer Science: Part A: Polymer Chemistry**

DOI 10.1002/pola
1,3,4-oxadiazole ring. In the first stage, the polymerization proceeded homogeneously throughout the reaction and afforded clear polymer solutions. All the hydrazide prepolymers precipitated in a fiber-like form when slowly pouring the resulting polymer solutions into methanol. The obtained poly(amine-hydrazide)s had inherent viscosities in the range of 0.39–0.44 dL/g with weight-average molecular weights ($M_w$) and degree of polymerization (DP) in the range of 23,100–28,500.

$^e$ Residual weight percentage at 800 °C in nitrogen.
Thermal conversion of the hydrazide group to the 1,3,4-oxadiazole ring was confirmed by elemental analysis and IR spectroscopy. As a representative study, a thin-film of polyhydrazide I-TPH was heated at 350 °C for 3 h, and the IR spectra are shown in Figure S1 in Supporting Information. After curing at 350 °C for 3 h, the complete conversion from polyhydrazide I-TPH to poly(amine-1,3,4-oxadiazole) IV-TPH could be confirmed by the disappearance of the absorption at 3271 (N–H), 1657 cm⁻¹ (amide carbonyl), and the appearance of characteristic 1,3,4-oxadiazole ring vibration at around 1488, 1602 (C═N), and 1072 (C–O–C). DSC also could be used to investigate the cyclization of hydrazide group to the oxadiazole structure. A typical pair of DSC curves of poly(amine-hydrazide) I-TPH and poly(amine-1,3,4-oxadiazole) IV-TPH are illustrated in Supporting Information Figure S2. The main endothermic peak revealed the cyclodehydration reaction of hydrazide group with water evolution in the range of 300–400 °C. The obtained poly(amine-1,3,4-oxadiazole)s had inherent viscosities in the range of 0.35–0.39 dL/g.

**Polymer Properties**

**Basic Characterizations**

The solubility behavior of all the polymers is shown in Supporting Information Table S2. These polymers with light-color exhibited good solubility in various solvents such as NMP, DMAc, DMF, dimethyl sulfoxide (DMSO), and m-cresol. Compared with phenyl- and naphthyl-based poly(amine-1,3,4-oxadiazole)s series, the enhanced solubility of anthryl-based IV series can be attributed to the introduction of bulky, asymmetry and noncoplanar 9-anthryldiphenylamine group into the repeat unit, which interrupt chain packing and decrease interchain interactions. Thus, the excellent solubility makes these polymers as potential candidates for practical applications by spin-coating or ink-jet printing processes.

The wide-angle X-ray diffraction studies of the poly(amine-hydrazide)s and poly(amine-1,3,4-oxadiazole)s indicated that all the polymers were essentially amorphous. The amorphous nature can be attributed to the introduction of bulky, twisted, three-dimensional 9-anthryldiphenylamine unit along the polymer backbone.

The thermal properties of poly(amine-hydrazide)s and poly(amine-1,3,4-oxadiazole)s are summarized in Table S2.
in Table 1. The glass-transition temperatures \( T_g \) of poly(amine-hydrazide)s and poly(amine-1,3,4-oxadiazole)s were observed in the range of 200–221 and 297–318 °C by DSC. Typical TGA curves for poly(amine-1,3,4-oxadiazole) IV-TPH are reproduced in Supporting Information Figure S3. All of the poly(amine-1,3,4-oxadiazole)s exhibited a similar TGA pattern with no significant weight loss below 500 °C in air or nitrogen atmosphere. The 10% weight-loss temperatures \( T_{10}^d \) of the poly(amine-1,3,4-oxadiazole)s in nitrogen and air were recorded in the range of 515–520 °C and 510–520 °C, respectively. The amount of carbonized residue (char yield) of these polymers was more than 55% at 800 °C in nitrogen. The high char yields of these polymers can be ascribed to their high aromatic content. As shown in Table 1, when compared with phenyl- and naphthyl-based poly(amine-1,3,4-oxadiazole)s, the anthryl-based IV series showed a higher \( T_g \) and better thermal stability due to the introduction of pendent anthracene groups in the repeat unit.

**Optical and Electrochemical Properties**

The optical properties of the poly(amine-hydrazide)s and poly(amine-1,3,4-oxadiazole)s were investigated by UV-vis and photoluminescence spectroscopy. The results are summarized in Table 2. These soluble polymers I-VI exhibited maximum UV-vis absorption bands at 344–391 nm in NMP solution, due to the \( \pi-\pi^* \) transitions of the aromatic chromophores, for example, anthracene units and phenyl rings. The UV-vis absorptions of anthrylamine-based poly(amine-hydrazide)s and poly(amine-1,3,4-oxadiazole)s in film state showed single absorbance at 356–357 and 375–382 nm, respectively. Figure 1 shows UV-vis absorption and photoluminescence spectra of poly(amine-hydrazide)s and poly(amine-1,3,4-oxadiazole)s in NMP solutions (Conc.: 10⁻⁵ M). These anthrylamine-based poly(amine-hydrazide) I-IPH and poly(amine-1,3,4-oxadiazole) IV-IPH exhibited green PL emission maximum at 490 nm in NMP solution with quantum yield of 29.9% and 13.5%, respectively. In film state, PL quantum yields of polymer I-IPH and IV-IPH were 17 and 12%, respectively. These polymers revealed large blue shift of maximum PL peak from solution to film state (as shown in Table 2), which could be attributed to the solvent effect that was found for the triphenylamine containing polymer system in our lab, and exhibited more red shift with increasing solvent polarity and symmetry. The photoluminescence behavior of poly(amine-hydrazide)s and poly(amine-1,3,4-oxadiazole)s in solution and film state by UV irradiation are shown in Figure 2. The cutoff wavelengths (absorption edge; \( \lambda_0 \)) from the UV-vis transmittance spectra showed...
light-color and high optical transparency with cutoff wavelength in the range of 415–435 nm (Supp. Info. Fig. S4).

The electrochemical properties of the poly(amine-hydrazide)s and poly(amine-1,3,4-oxadiazole)s were investigated by CV and DPV. The results are summarized in Table 3. The redox behavior of these polymers was investigated by CV conducted for the cast films on an ITO-coated glass substrate in dry CH₃CN and DMF containing 0.1 M TBAP as an electrolyte under nitrogen atmosphere for oxidation and reduction measurements. Figure 3 shows the typical CV for poly(amine-hydrazide) I-TPH and poly(amine-1,3,4-oxadiazole) IV-TPH. Figure 4 shows the differential pulse voltammograms of the anthrylamine-based polymer films. It shows clearly that there is an overlap of peak potential for IV-TPH. Comparing with I-TPH, the second reduction behavior of IV-TPH might occur on the anthracene group. Therefore, the first and third reduction behaviors of IV-TPH were assumed to occur on the oxadiazole moieties. In addition, the first and second reduction stage of IV-TPH could be assigned to the anthracene and oxadiazole units, respectively. The mechanism for the electrochemical reduction of poly(amine-hydrazide)s and poly(amine-1,3,4-oxadiazole)s could be depicted as in Schemes 2 and 3, respectively. In addition, the oxidation potentials of poly(amine-hydrazide)s were almost the same as the corresponding poly(amine-1,3,4-oxadiazole)s that also could explain these polymers with donor acceptor moieties are isolated system. The energy of the highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) levels of the corresponding polymers can be determined from the oxidation onset, reduction onset potentials (E_{onset}) and the onset absorption wavelength, and the results were listed in Table 3.

For example, the oxidation/reduction onset for poly(amine-hydrazide) I-TPH has been determined as 1.07/1.46 (V versus Ag/AgCl). The external ferrocene/ferrocenium (Fc/Fc⁺) redox standard E_{1/2} is 0.44 V versus Ag/AgCl in CH₃CN. Assuming that the HOMO energy for the Fc/Fc⁺ standard is 4.80 eV with respect to the zero vacuum level, the HOMO and LUMO energies for

Figure 3. Cyclic Voltammograms of poly(amine-hydrazide) (a) I-TPH, and poly(amine-1,3,4-oxadiazole) (b) IV-TPH films onto an indium-tin oxide (ITO)-coated glass substrate in CH₃CN (oxidation) and DMF (reduction) solution containing 0.1 M TBAP at scan rate of 50 and 100 mV/s, respectively.

DOI 10.1002/pola
polymer I-TPH could be evaluated to be 5.43 and 2.90 eV, respectively. Thus, the HOMO and LUMO energy for poly(amine-1,3,4-oxadiazole) IV-TPH could also be evaluated to be 5.46 and 2.96 eV, respectively.

**Electrochromic Characteristics**

Electrochromism of the poly(amine-1,3,4-oxadiazole)s thin films was examined by an optically transparent thin-layer electrode (OTTLE) coupled with UV-vis spectroscopy. The electrode preparations and solution conditions were identical to those used in CV. The typical electrochromic absorption spectra of poly(amine-1,3,4-oxadiazole) IV-TPH are shown in Figure 5. Figure 6 shows the three-dimensional % transmittance-wavelength-applied potential correlations of this sample. When the applied potentials decreased negatively from 0.00 to −2.20 V, the peak of characteristic absorbance at 376 nm for poly(amine-1,3,4-oxadiazole) IV-TPH decreased gradually while one new bands grew up at 511 nm due to the electron reduction. The new spectrum was assigned as that of the anionic radical poly(amine-1,3,4-oxadiazole) was generated and exhibited strong bands as determined by UV-vis spectroelectrochemical methods. Meanwhile, color of the film changed from original pale yellow to a red reduced form. Polymer IV-IPH exhibited highly contrast of optical transmittance change (ΔT %) up to 65% in 511 nm. The coloration

E<sub>E<sup>BC</sup></sub> (Electrochemical band gap): Difference between E<sub>HOMO</sub> and E<sub>LUMO</sub>.  
E<sub>E<sup>Opt</sup></sub> (Optical band gap): Calculated from polymer films (E<sub>E<sup>Opt</sup></sub> = 1240/λ<sub>onset</sub>).  
E<sub>E<sup>EC</sup></sub> LUMO (LUMO energy levels calculated from optical method): Difference between E<sub>HOMO</sub> and E<sub>E<sup>Opt</sup></sub>.  
<sup>a</sup> vs. Ag/AgCl in CH<sub>3</sub>CN.  
<sup>b</sup> vs. Ag/AgCl in DMF.  
<sup>c</sup> The HOMO and LUMO energy levels were calculated from cyclic voltammetry and were referenced to ferrocene (4.8 eV).  
<sup>d</sup> No discernible signal was observed.

The coloration of the film changed from original pale yellow to a red reduced form. Polymer IV-IPH exhibited highly contrast of optical transmittance change (ΔT %) up to 65% in 511 nm. The coloration...
efficiency at 511 nm is as high as ca. 122 cm²/C with high optical density change (ΔOD₅₁₁) up to 0.52, determined from the in situ experiments.¹⁶

**CONCLUSIONS**

A series of aromatic poly(amine-hydrazide)s were prepared from the dicarboxylic acid with terephthalic dihydrazide (TPH) and isophthalic dihydrazide (IPH), respectively, via the Yamazaki phosphorylation reaction, and were thermally cyclodehydrated into the corresponding poly(amine-1,3,4-oxadiazole)s. The introduction of the bulky anthracene group into the polymer backbone disrupts the coplanarity of aromatic units in chain packing which increases the between-chains spaces or free volume thus enhancing solubility and thermal stability of the formed poly(amine-1,3,4-oxadiazole)s. All the amorphous polymers exhibited high optical transparency from UV-vis transmittance measurement with cutoff wavelength in the range of 415–435 nm. The poly(amine-hydrazide) I-IPH and poly(amine-1,3,4-oxadiazole) IV-IPH exhibited green fluorescence emission maximum at 490 nm in

NMP solution with high quantum yield of 29.9% and 13.5% due to the anthrylamine chromophores. The anthrylamine-based poly(amine-1,3,4-oxadiazole)s revealed electrochromic characteristics with changing color from the pale yellow neutral form to the red reduced form when scanning potentials negatively from 0.00 to −2.20 V. Thus, these novel anthrylamine-based poly(amine-hydrazide)s and poly(amine-1,3,4-oxadiazole)s have great potential as a new type organo-processable green-light-emitting and electrochromic materials due to their excellent thermal stability, solubility, quantum efficiency, and electrochemical behavior.

The authors are grateful to the National Science Council of the Republic of China for its financial support of this work. The technical assistance on the PL quantum yield measurement from Prof. Ken-Tsung Wong of National Taiwan University is highly appreciated.
