Chapter 4 Network Layer: The Data Plane

A note on the use of these Powerpoint slides:

We' re making these slides freely available to all (faculty, students, readers). They're in PowerPoint form so you see the animations; and can add, modify, and delete slides (including this one) and slide content to suit your needs. They obviously represent a *lot* of work on our part. In return for use, we only ask the following:

- If you use these slides (e.g., in a class) that you mention their source (after all, we'd like people to use our book!)
- If you post any slides on a www site, that you note that they are adapted from (or perhaps identical to) our slides, and note our copyright of this material.

Thanks and enjoy! JFK/KWR

Computer Networking: A Top Down Approach

7th Edition, Global Edition Jim Kurose, Keith Ross Pearson April 2016

Chapter 4: network layer

chapter goals:

- understand principles behind network layer services, focusing on data plane:
 - network layer service models
 - forwarding versus routing
 - how a router works
 - Focusing on forwarding
- instantiation, implementation in the Internet

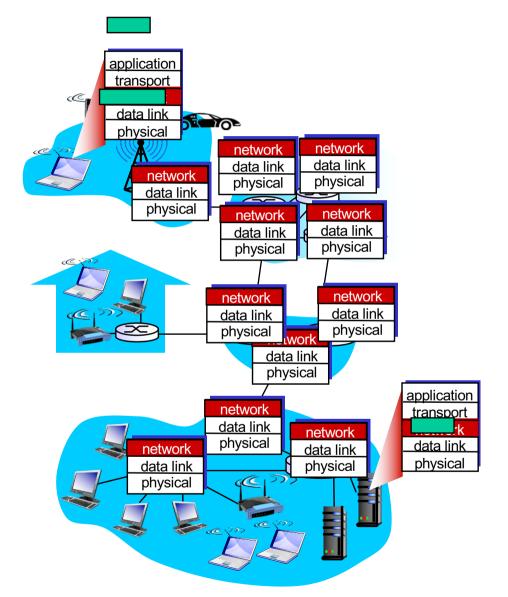

Chapter 4: outline

- 4.1 Overview of Network layer
 - data plane
 - control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - network address translation
 - IPv6

- 4.4 Generalized Forward and SDN
 - match
 - action
 - OpenFlow examples of match-plus-action in action

Network layer

- transport segment from sending to receiving host
- network layer protocols in every host, router
- on sending side encapsulates segments into datagrams
- router examines header fields in all IP datagrams passing through it
- on receiving side, delivers segments to transport layer

Two key network-layer functions

network-layer functions:
 forwarding: move packets
from router's input to
appropriate router output

routing: determine route taken by packets from source to destination

routing algorithms

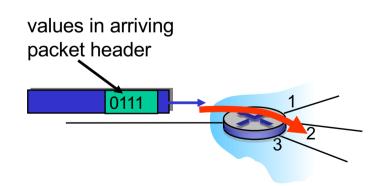

analogy: taking a trip

- forwarding: process of getting through single interchange
- routing: process of planning trip from source to destination

Network layer: data plane, control plane

Data plane

- Iocal, per-router function
- determines how datagram arriving on router input port is forwarded to router output port
- forwarding function

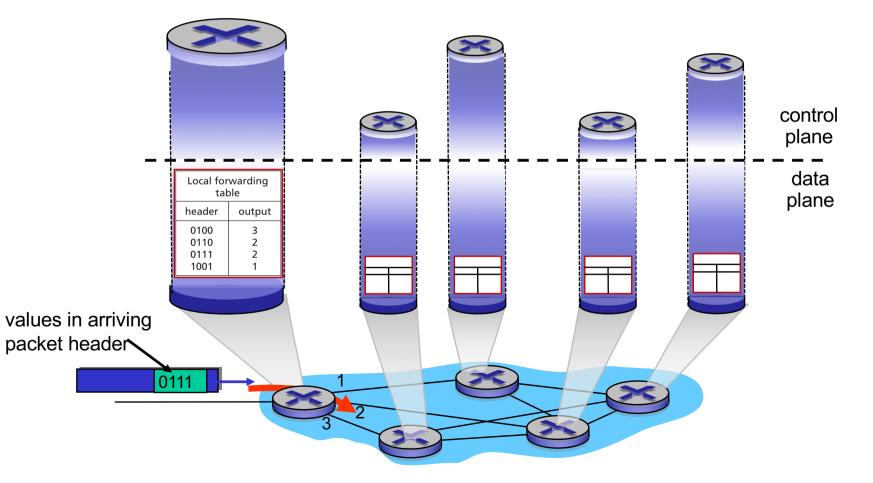

Control plane

- network-wide logic
- determines how datagram is routed among routers along end-end path from source host to destination host
- two control-plane approaches:
 - *traditional routing algorithms:* implemented in routers
 - software-defined networking (SDN): implemented in (remote) servers

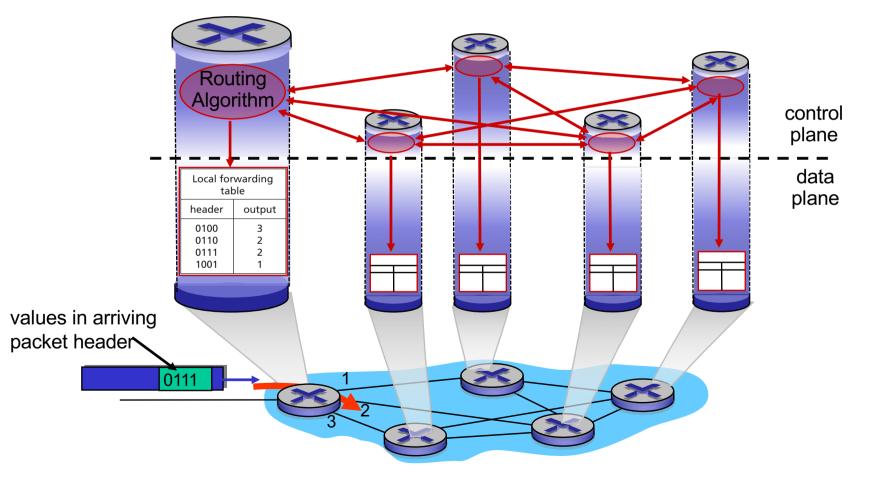

Per-router data plane

Forwarding table to allow fast output interface lookup

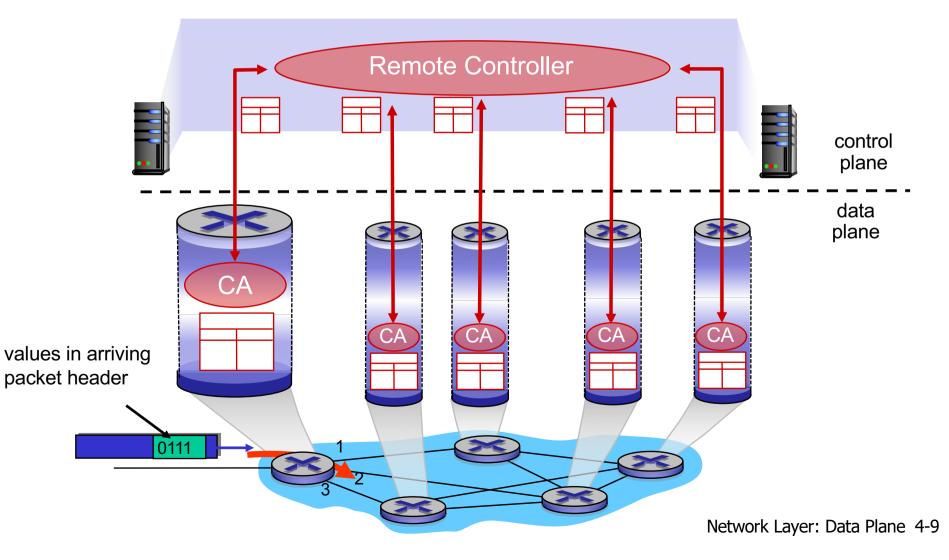

Network-wide logic in control plane

Traditional: Individual routing algorithm components *in each and every router* interact in the control plane

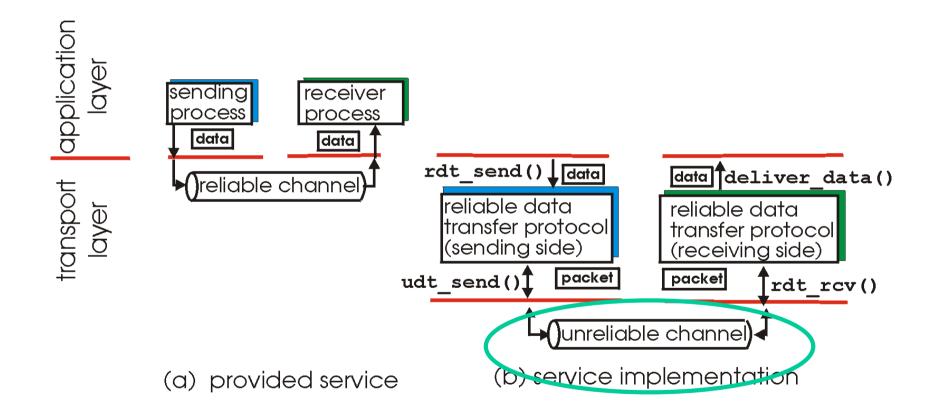

Logically centralized control plane

SDN: A distinct (typically remote) controller interacts with local control agents (CAs)

Remember This?

Connectionless service

- best effort:
 - TCP/IP (aka. the Internet)
- two end hosts and intervening routers do not set up any 'connection specific' states before forwarding datagrams

Connection oriented service

- 3rd important function in *some* network architectures:
 - ATM, frame relay, X.25
- before datagrams flow, two end hosts and intervening routers establish connection
 - routers get involved

- network vs transport layer connection service:
 - network: between two hosts (may also involve inervening routers)
 - transport: between two processes

Network service model

Q: What service model for "channel" transporting datagrams from sender to receiver?

example services for individual datagrams:

- guaranteed delivery
- guaranteed delivery with less than 40 msec delay

example services for a flow of datagrams:

- in-order datagram delivery
- guaranteed minimum bandwidth to flow
- restrictions on changes in inter-packet spacing

Network layer service models:

1	Network	Service	Guarantees ?				Congestion
Architecture	Model	Bandwidth	Loss	Order	Timing	feedback	
	Internet	best effort	none	no	no	NO	no (inferred via loss)
	ATM	CBR	constant rate	yes	yes	yes	no congestion
	ATM	VBR	guaranteed rate	yes	yes	yes	no congestion
	ATM	ABR	guaranteed minimum	no	yes	no	yes
	ATM	UBR	none	no	yes	no	no

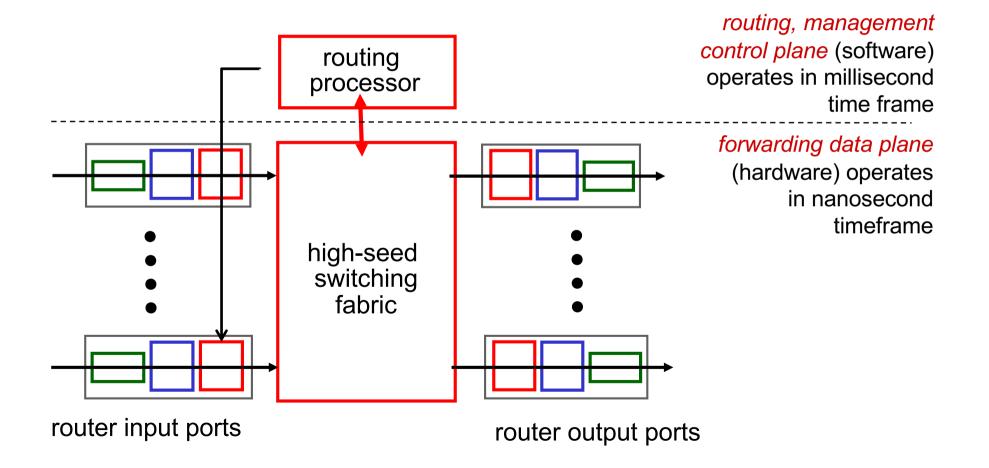

Chapter 4: outline

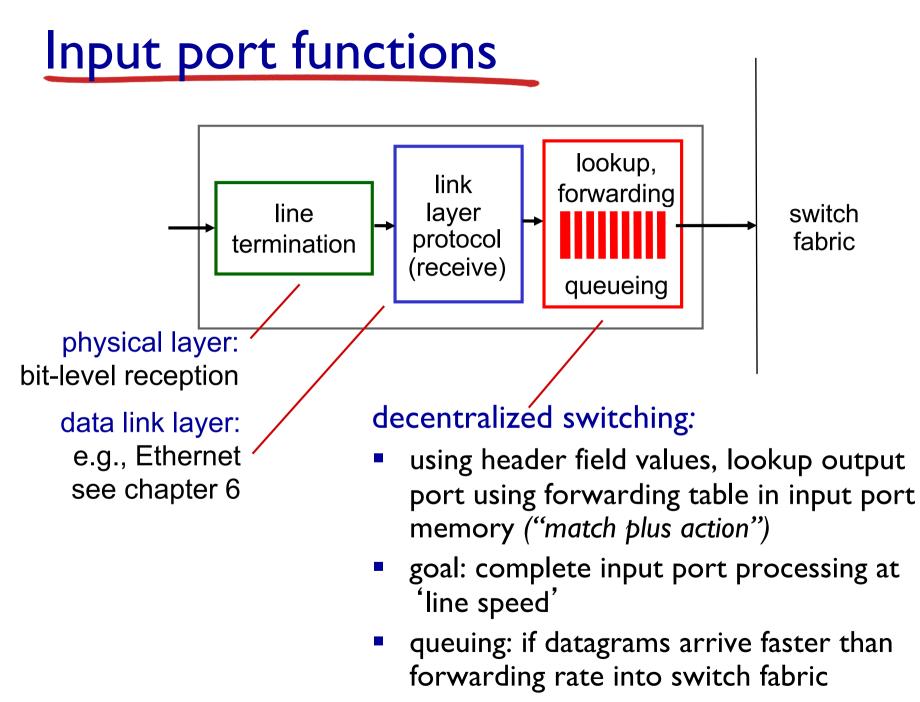

- 4.1 Overview of Network layer
 - data plane
 - control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - network address translation
 - IPv6

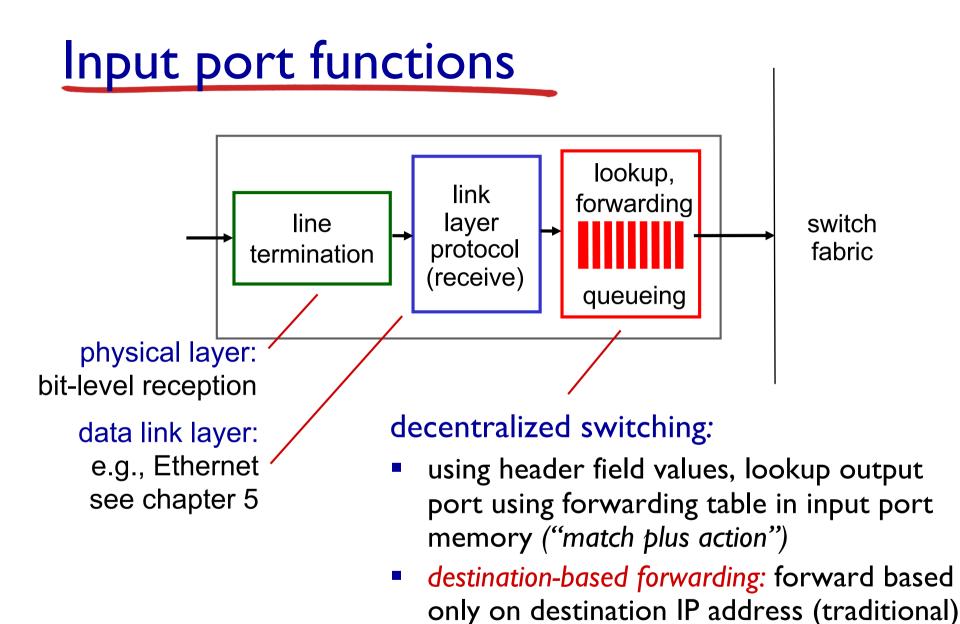

- 4.4 Generalized Forward and SDN
 - match
 - action
 - OpenFlow examples of match-plus-action in action

Router architecture overview

high-level view of generic router architecture:

 generalized forwarding: forward based on any set of header field values

Destination-based forwarding

forwarding table							
Destinatio	Link Interface						
through		00010000		0			
through		00011000		1			
		00011000		2			
11001000 otherwise	00010111	00011111	11111111	3			

Q: How many entries?

Longest prefix matching

- longest prefix matching

when looking for forwarding table entry for given destination address, use *longest* address prefix that matches destination address.

Destination Address Range	Link interface
11001000 00010111 00010*** ********	0
11001000 00010111 00011000 ********	1
11001000 00010111 00011*** *******	2
otherwise	3

examples:

DA: 11001000 00010111 00010110 10100001

DA: 11001000 00010111 00011000 10101010

which interface? which interface?

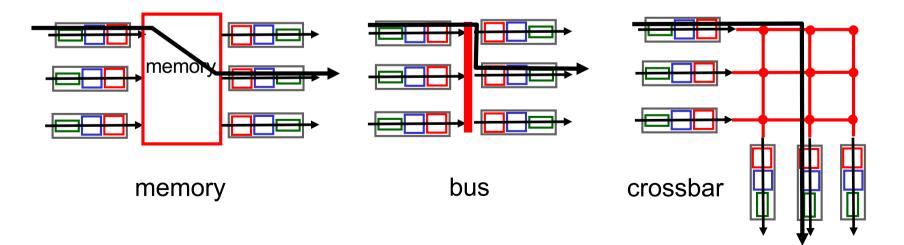

Double Quiz Time!

Longest prefix matching

- we'll see why longest prefix matching is used shortly, when we study addressing
- longest prefix matching: often performed using ternary content addressable memories (TCAMs)
 - content addressable: present dest address to TCAM: retrieve link interface in one clock cycle, regardless of table size
 - Cisco Catalyst: can store up ~IM routing table entries in TCAM

Switching fabrics

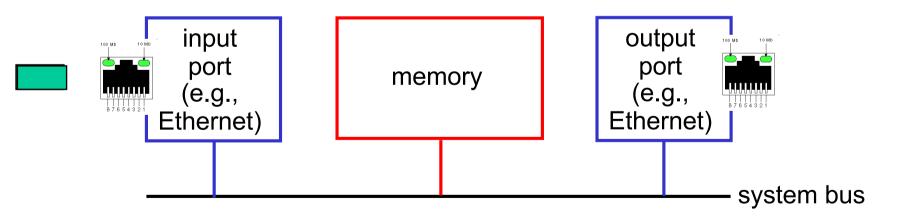

- transfer packet from input buffer to appropriate output buffer
- switching rate: rate at which packets can be transfer from inputs to outputs
 - often measured as multiple of input/output line rate
 - N inputs: switching rate N times line rate desirable
- three types of switching fabrics

Switching via memory

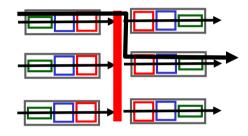

first generation routers:

- traditional computers with switching under direct control of CPU
- packet copied to system's memory
- speed limited by memory bandwidth (2 bus crossings per datagram)

Switching via a bus

- datagram from input port memory to output port memory via a shared bus
- bus contention: switching speed limited by bus bandwidth

 32 Gbps bus, Cisco 5600: sufficient speed for access and enterprise routers

bus

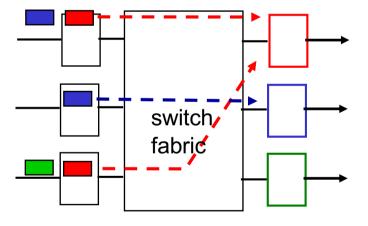

Switching via interconnection network

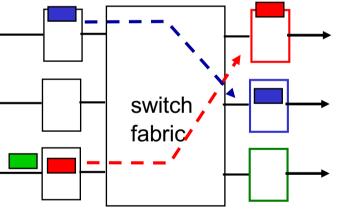

- overcome bus bandwidth limitations
- banyan networks, crossbar, other interconnection nets initially developed to connect processors in multiprocessor computer
- advanced design: fragmenting datagram into fixed length cells, switch cells through the fabric.
- Cisco I2000: switches 60 Gbps through the interconnection network

Input port queuing

- fabric slower than input ports combined -> queueing may occur at input queues
 - queueing delay and loss due to input buffer overflow!
- Head-of-the-Line (HOL) blocking: queued datagram at front of queue prevents others in queue from moving forward

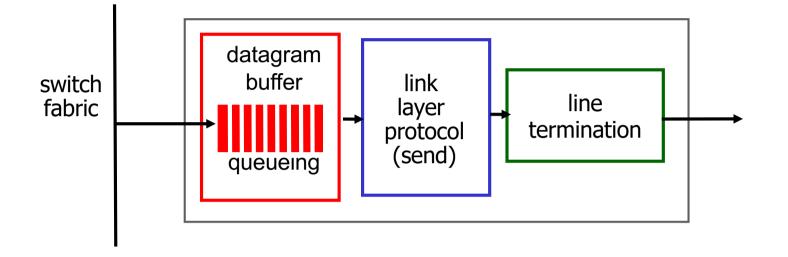

output port contention: only one red datagram can be transferred. lower red packet is blocked one packet time later: green packet experiences HOL blocking

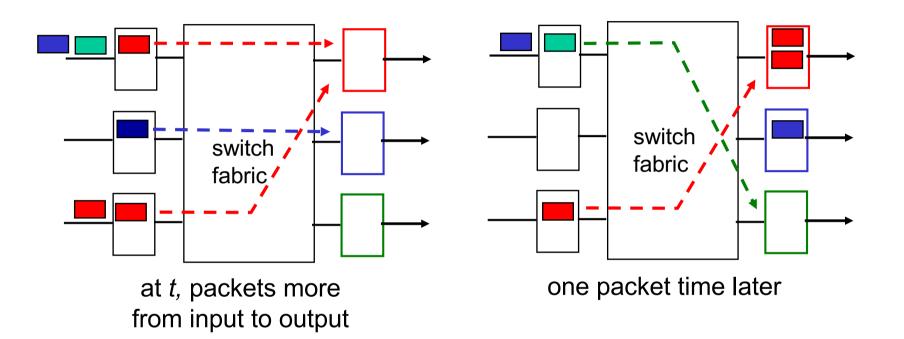

This slide in HUGELY important!

- buffering required from fabric faster rate
 Datagram (packets) can be dropped due to congestion, lack of buffers
- scheduling Priority scheduling who gets best datagrams performance, network neutrality

Output port queueing

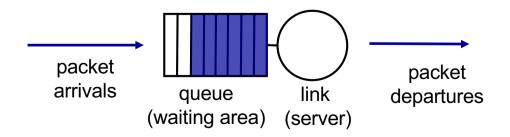

- buffering when arrival rate via switch exceeds output line speed
- queueing (delay) and loss due to output port buffer overflow!

How much buffering?

- RFC 3439 rule of thumb: average buffering equal to "typical" RTT (say 250 msec) times link capacity C
 - e.g., C = 10 Gpbs link: 2.5 Gbit buffer
- recent recommendation: with N flows, buffering equal to

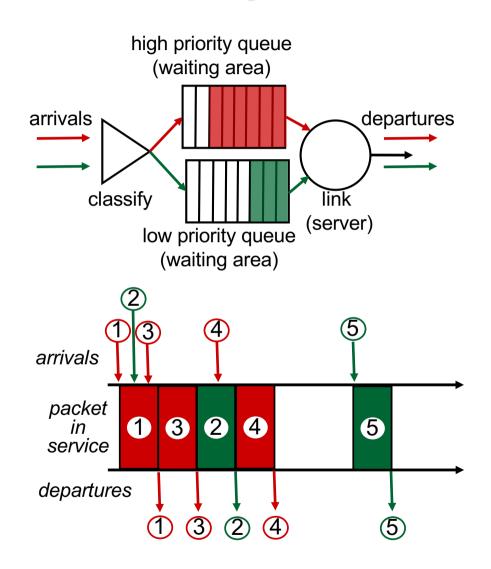

Scheduling mechanisms

- scheduling: choose next packet to send on link
- FIFO (first in first out) scheduling: send in order of arrival to queue
 - real-world example?
- discard policy: if packet arrives to full queue: who to discard?
 - *tail drop:* drop arriving packet
 - *priority*: drop/remove on priority basis
 - *random*: drop/remove randomly

Scheduling policies: priority

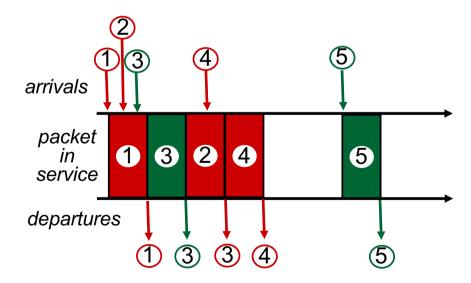

- priority scheduling: send highest priority queued packet
- multiple *classes*, with different priorities
 - class may depend on marking or other header info, e.g. IP source/dest, port numbers, etc.
 - real world example?

Scheduling policies: still more

Round Robin (RR) scheduling:

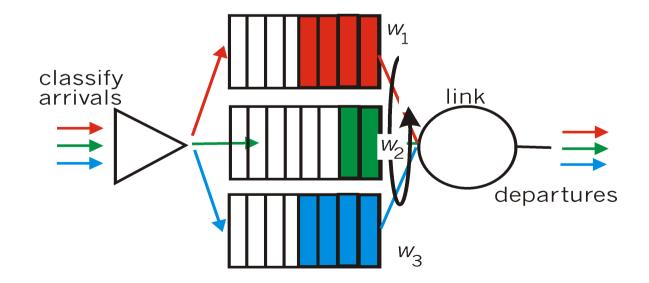

- multiple classes
- cyclically scan class queues, sending one complete packet from each class (if available)
- real world example?

Scheduling policies: still more

Weighted Fair Queuing (WFQ):

- generalized Round Robin
- each class gets weighted amount of service in each cycle
- real-world example?

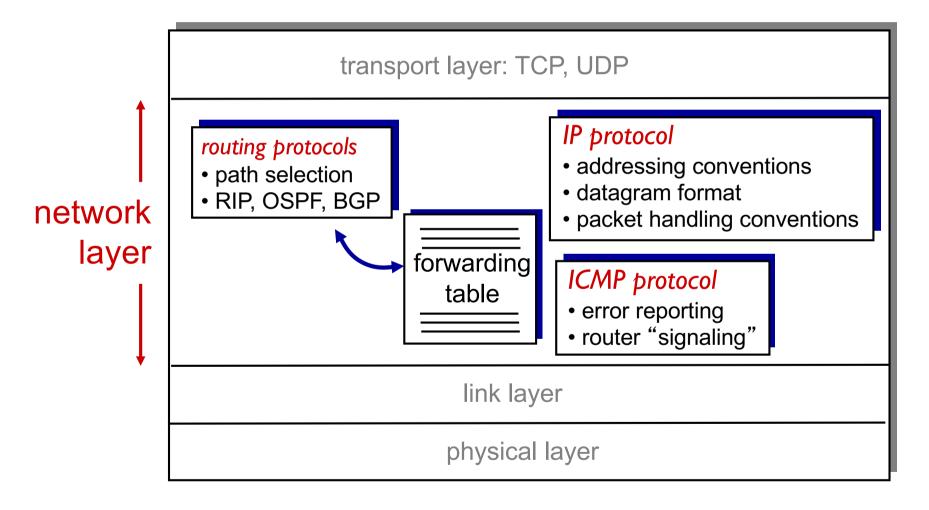

Chapter 4: outline

- 4.1 Overview of Network layer
 - data plane
 - control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - network address translation
 - IPv6

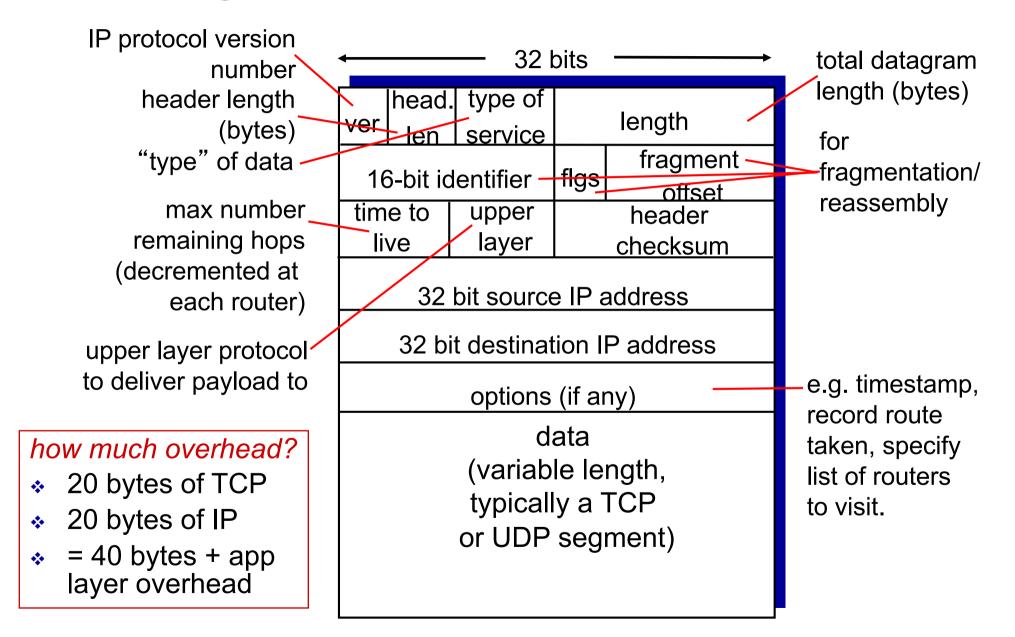

- 4.4 Generalized Forward and SDN
 - match
 - action
 - OpenFlow examples of match-plus-action in action

The Internet network layer

host, router network layer functions:

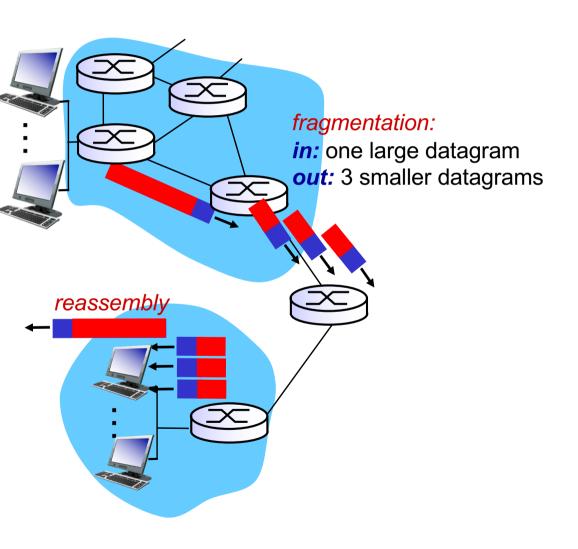

IP datagram format

IP fragmentation, reassembly

- network links have MTU (max.transfer size) largest possible link-level frame
 - different link types, different MTUs
- large IP datagram divided ("fragmented") within net
 - one datagram becomes several datagrams
 - "reassembled" only at final destination
 - IP header bits used to identify, order related fragments

IP fragmentation, reassembly

example:	lengthIDfragflagoffset=4000=x=0=0				
 4000 byte datagram MTU = 1500 bytes 	one large datagram becomes several smaller datagrams				
1480 bytes in data field	lengthIDfragflagoffset=1500=x=1=0				
offset = 1480/8	lengthIDfragflagoffset=1500=x=1=185				
	length ID fragflag offset =1040 =x =0 =370				

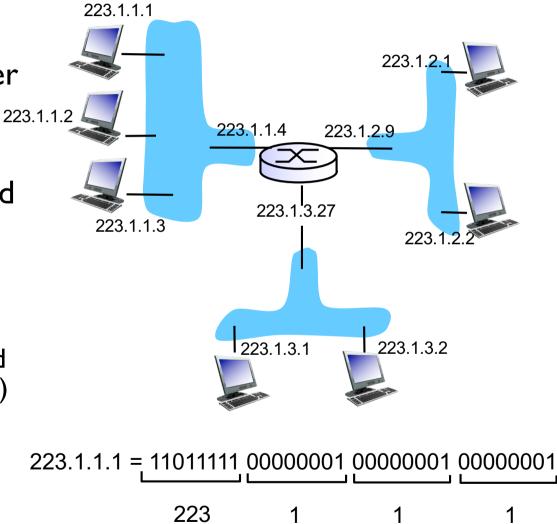

Chapter 4: outline

- 4.1 Overview of Network layer
 - data plane
 - control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - network address translation
 - IPv6

- 4.4 Generalized Forward and SDN
 - match
 - action
 - OpenFlow examples of match-plus-action in action

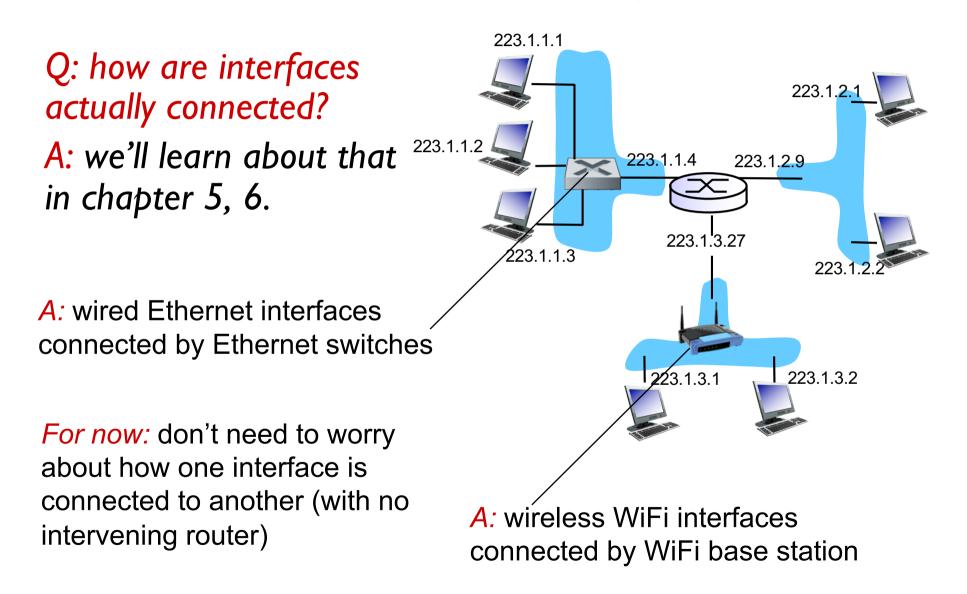

IP addressing: introduction

- IP address: 32-bit identifier for host, router interface
- interface: connection between host/router and physical link
 - router's typically have multiple interfaces
 - host typically has one or two interfaces (e.g., wired Ethernet, wireless 802.11)
- IP addresses associated with each interface

Network Layer: Data Plane 4-41

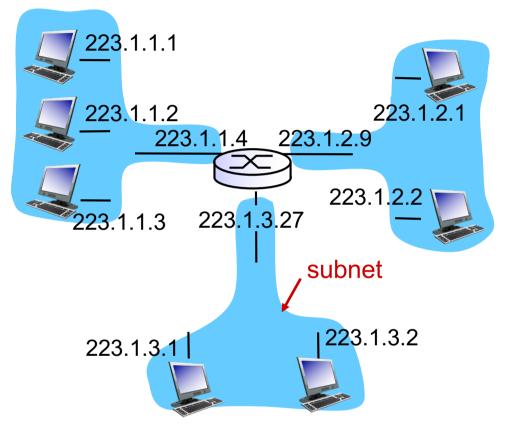

IP addressing: introduction

Subnets

IP address:

- subnet part high order bits
- host part low order bits
- what 's a subnet ?
 - can physically reach each other without intervening router
 - interfaces on the same subnet having the same subnet address

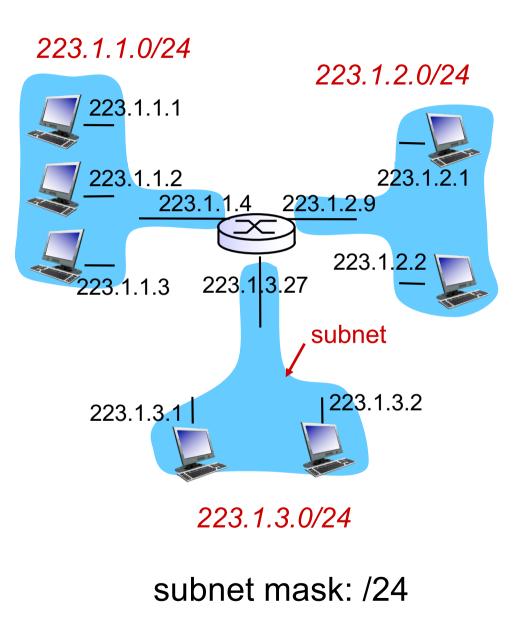

network consisting of 3 subnets

Subnets

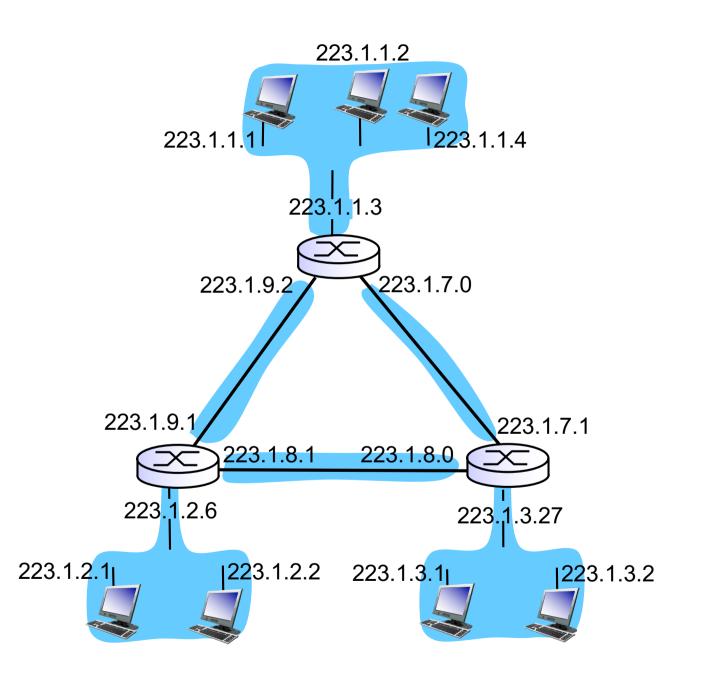

recipe

- to determine the subnets, detach each interface from its host or router, creating islands of isolated networks
- each isolated network is called a subnet

how many?

IP addressing: CIDR

CIDR: Classless InterDomain Routing

- subnet portion of address of arbitrary length
- address format: a.b.c.d/x, where x is # bits in subnet portion of address

200.23.16.0/23

Quiz Time!

IP addresses: how to get one?

Q: How does a *host* get IP address?

- hard-coded by system admin in a file
 - Windows: control-panel->network->configuration->tcp/ip->properties
 - UNIX: /etc/rc.config
- DHCP: Dynamic Host Configuration Protocol: dynamically get address from a server
 - "plug-and-play"

DHCP: Dynamic Host Configuration Protocol

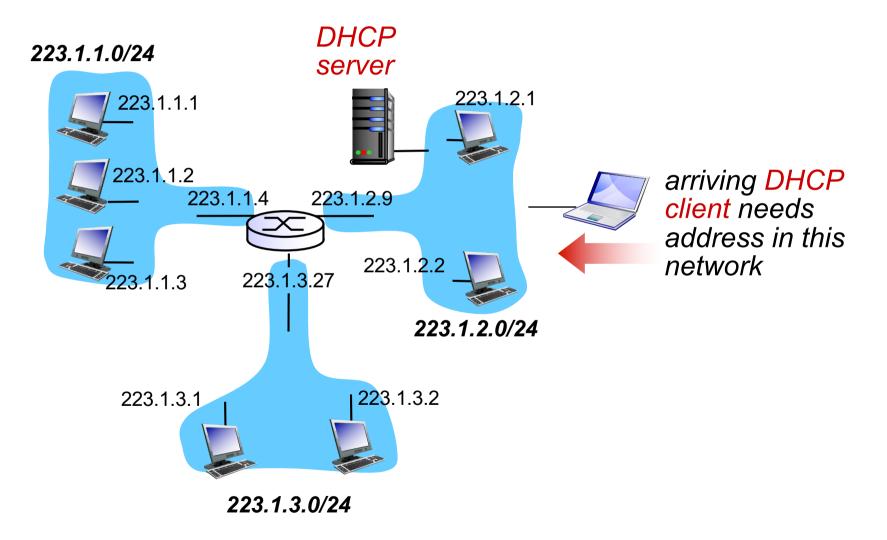

goal: allow host to dynamically obtain its IP address from network server when it joins network

- can renew its lease on address in use
- allows reuse of addresses (only hold address while connected/"on")
- support for mobile users who want to join network (more shortly)

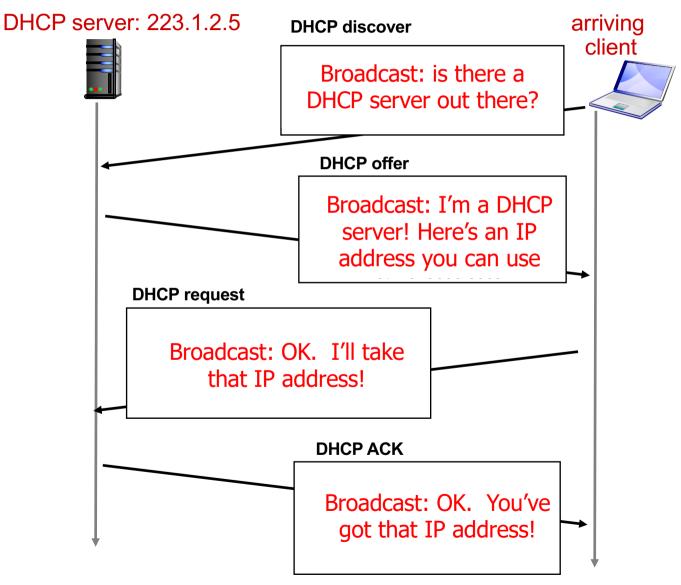

DHCP overview:

- host broadcasts "DHCP discover" msg [optional]
- DHCP server responds with "DHCP offer" msg [optional]
- host requests IP address: "DHCP request" msg
- DHCP server sends address: "DHCP ack" msg

DHCP client-server scenario

DHCP client-server scenario

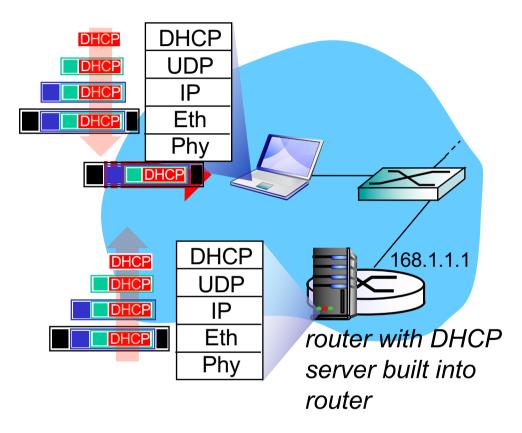

DHCP: more than IP addresses

DHCP can return more than just allocated IP address on subnet:

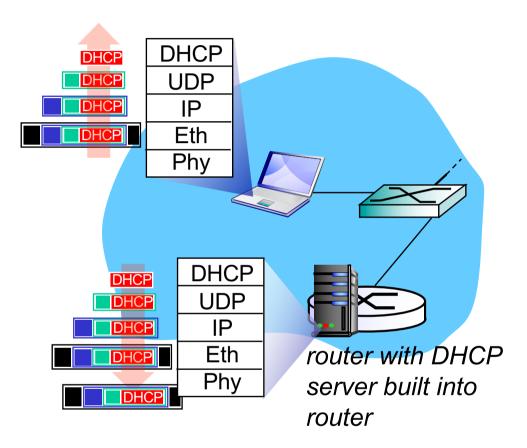

- address of first-hop router for client
- name and IP address of DNS sever
- network mask (indicating subnet versus host portion of address)

DHCP: example

- connecting laptop needs its IP address, addr of first-hop router, addr of DNS server: use DHCP
- DHCP request encapsulated in UDP, encapsulated in IP, encapsulated in 802.3 Ethernet
- Ethernet frame broadcast (dest: FFFFFFFFFF) on LAN, received at router running DHCP server
- Ethernet demuxed to IP demuxed to UDP demuxed to DHCP

DHCP: example

- DHCP server formulates DHCP ACK containing client's IP address, IP address of first-hop router for client, name & IP address of DNS server
- encapsulation of DHCP server, frame forwarded to client, demuxing up to DHCP at client
- client now knows its IP address, name and IP address of DSN server, IP address of its first-hop router

DHCP: Wireshark output (home LAN)

Message type: Boot Request (1) Hardware type: Ethernet Hardware address length: 6 request Hops: 0 Transaction ID: 0x6b3a11b7 Seconds elapsed: 0 Bootp flags: 0x0000 (Unicast) Client IP address: 0.0.0.0 (0.0.0.0) Your (client) IP address: 0.0.0.0 (0.0.0.0) Next server IP address: 0.0.0.0 (0.0.0.0) Relay agent IP address: 0.0.0.0 (0.0.0.0) Client MAC address: Wistron 23:68:8a (00:16:d3:23:68:8a) Server host name not given Boot file name not given Magic cookie: (OK) Option: (t=53,l=1) **DHCP Message Type = DHCP Request** Option: (61) Client identifier Length: 7; Value: 010016D323688A; Hardware type: Ethernet Client MAC address: Wistron 23:68:8a (00:16:d3:23:68:8a) Option: (t=50,I=4) Requested IP Address = 192.168.1.101 Option: (t=12,I=5) Host Name = "nomad" **Option: (55) Parameter Request List** Length: 11; Value: 010F03062C2E2F1F21F92B 1 = Subnet Mask; 15 = Domain Name 3 = Router; 6 = Domain Name Server 44 = NetBIOS over TCP/IP Name Server

Quiz Time!

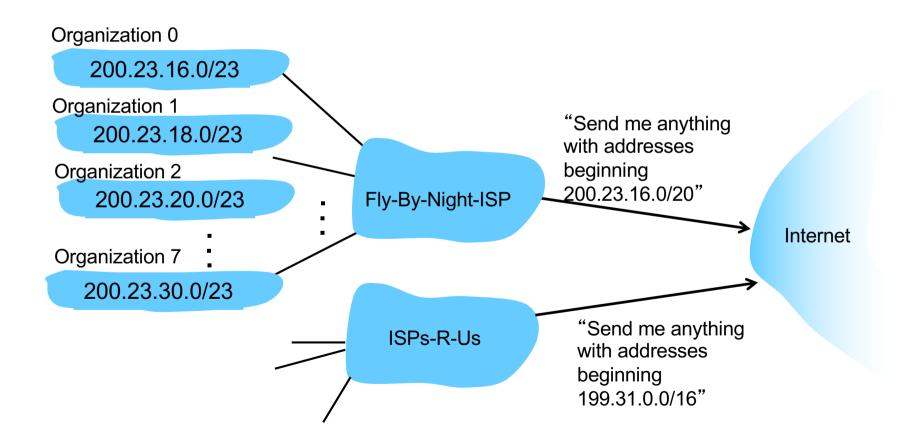

IP addresses: how to get one?

Q: how does a subnet get subnet part of IP addr?
A: gets allocated portion of its provider ISP's address space

ISP's block	<u>11001000</u>	00010111	00010000	00000000	200.23.16.0/20
Organization 0 Organization 1 Organization 2		00010111	00010010	00000000	200.23.16.0/23 200.23.18.0/23 200.23.20.0/23
Organization 7	<u>11001000</u>	00010111	<u>0001111</u> 0	0000000	200.23.30.0/23

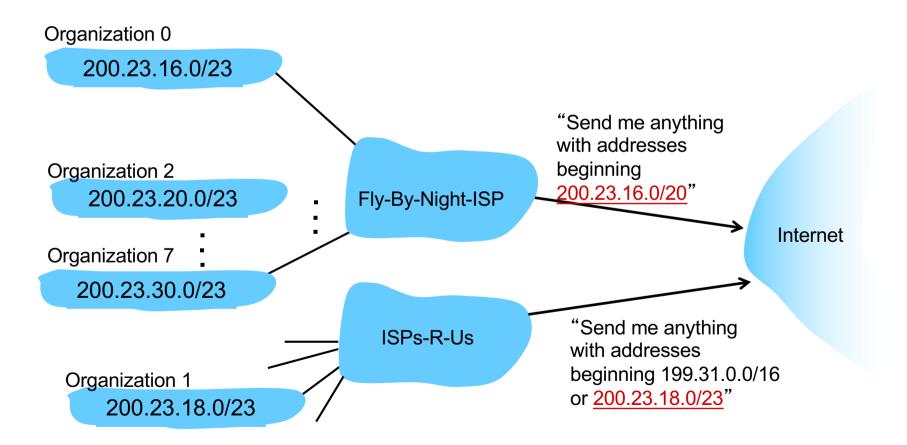

Hierarchical addressing: route aggregation

hierarchical addressing allows efficient advertisement of routing information:

Hierarchical addressing: more specific routes

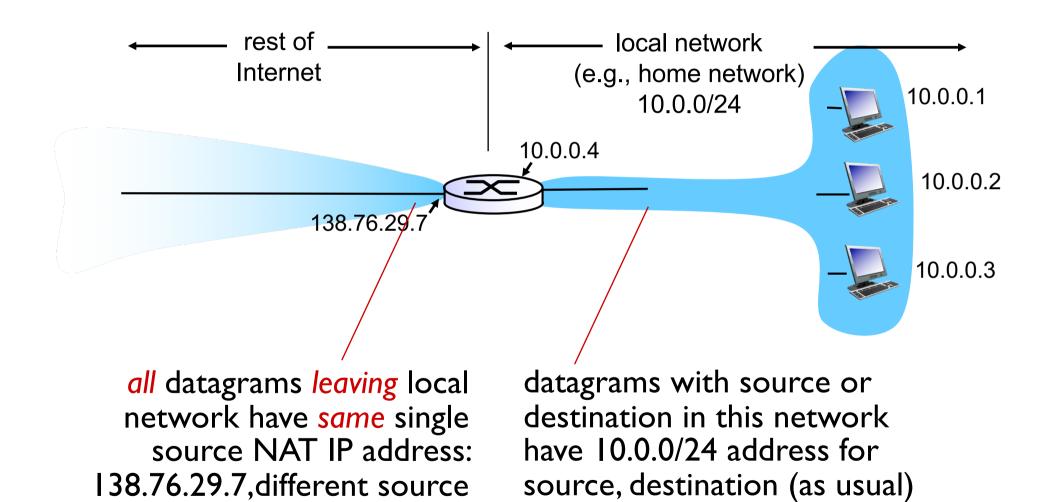

ISPs-R-Us has a more specific route to Organization I

IP addressing: the last word...

Q: how does an ISP get block of addresses?

- A: ICANN: Internet Corporation for Assigned
 - Names and Numbers http://www.icann.org/
 - allocates addresses
 - manages DNS
 - assigns domain names, resolves disputes

port numbers

Network Layer: Data Plane 4-61

motivation: local network uses just one IP address as far as outside world is concerned:

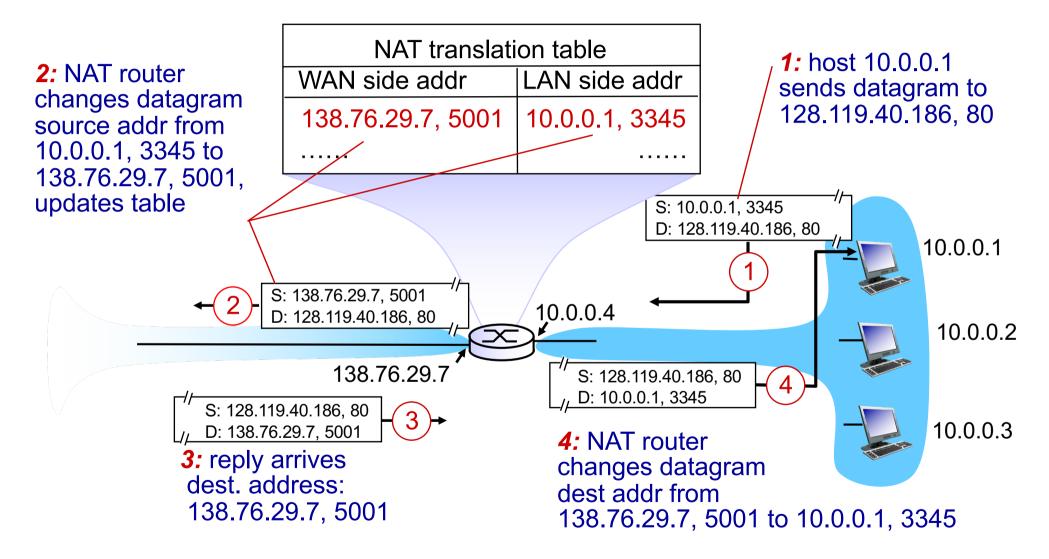

- range of addresses not needed from ISP: just one IP address for all devices
- can change addresses of devices in local network without notifying outside world
- can change ISP without changing addresses of devices in local network
- devices inside local net not explicitly addressable, visible by outside world (a security plus)

implementation: NAT router must:

- outgoing datagrams: replace (source IP address, port #) of every outgoing datagram to (NAT IP address, new port #)
- remember (in NAT translation table) every (source IP address, port #) to (NAT IP address, new port #) translation pair

... remote clients/servers will respond using (NAT IP address, new port #) as destination addr

 incoming datagrams: replace (NAT IP address, new port #) in dest fields of every incoming datagram with corresponding (source IP address, port #) stored in NAT table

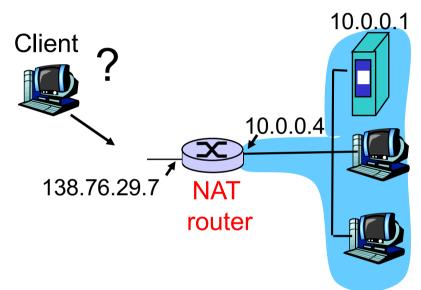

* Check out the online interactive exercises for more examples: http://gaia.cs.umass.edu/kurose_ross/interactive/

- I6-bit port-number field:
 - 60,000 simultaneous connections with a single LAN-side address!
- NAT is controversial:
 - routers should only process up to layer 3
 - address shortage should be solved by IPv6
 - NAT traversal: what if client wants to connect to server behind NAT?
 - NAT possibility must be taken into account by app designers, e.g., P2P applications
 - violates end-to-end argument

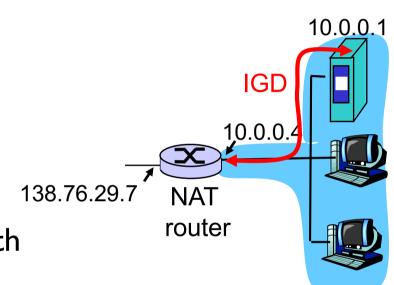

NAT traversal problem

- client want to connect to server with address 10.0.0.1
 - server address 10.0.0.1 local to LAN (client can't use it as destination addr)
 - only one externally visible NATted address: 138.76.29.7
- solution I: manually configure NAT to forward incoming connection requests at given port to server
 - e.g., (138.76.29.7, port 2500) always forwarded to 10.0.0.1 port 25000

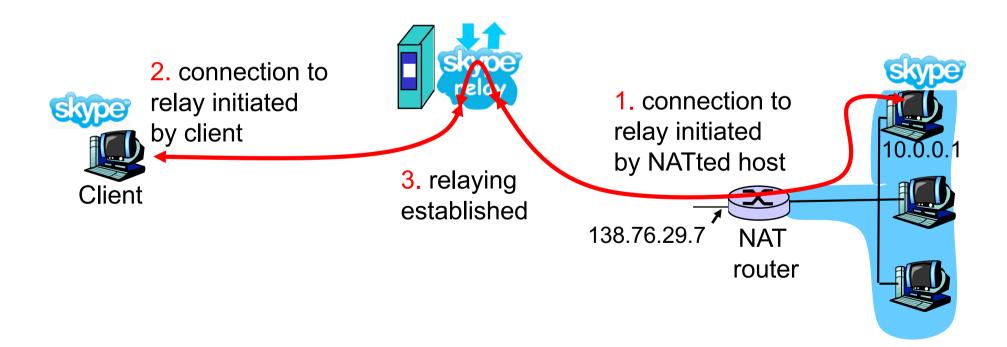

NAT traversal problem

- solution 2: Universal Plug and Play (UPnP) Internet Gateway Device (IGD) Protocol. Allows NATted host to:
 - learn public IP address
 (138.76.29.7)
 - enumerate existing port mappings
 - *add/remove port mappings (with lease times)
 - i.e., automatic NAT port map configuration

NAT traversal problem

- solution 3: relaying (used in Skype)
 - NATed server establishes connection to relay
 - External client connects to relay
 - relay bridges packets between to connections

Chapter 4: outline

- 4.1 Overview of Network layer
 - data plane
 - control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - network address translation
 - IPv6

- 4.4 Generalized Forward and SDN
 - match
 - action
 - OpenFlow examples of match-plus-action in action

IPv6: motivation

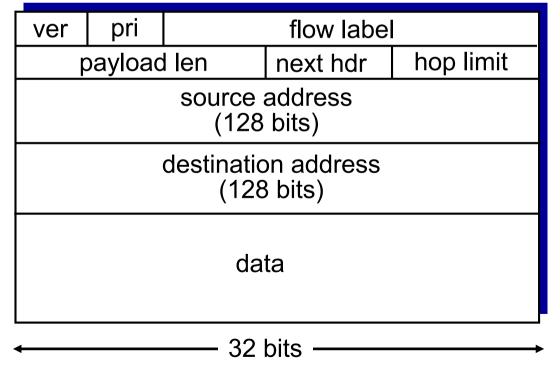

- initial motivation: 32-bit address space soon to be completely allocated.
- additional motivation:
 - header format helps speed processing/forwarding
 - header changes to facilitate QoS

IPv6 datagram format:

- fixed-length 40 byte header
- no fragmentation allowed

IPv6 datagram format

priority: identify priority among datagrams in flow flow Label: identify datagrams in same "flow." (concept of "flow" not well defined). next header: identify upper layer protocol for data

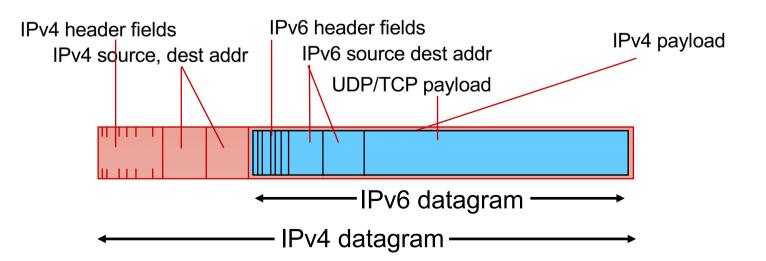

Other changes from IPv4

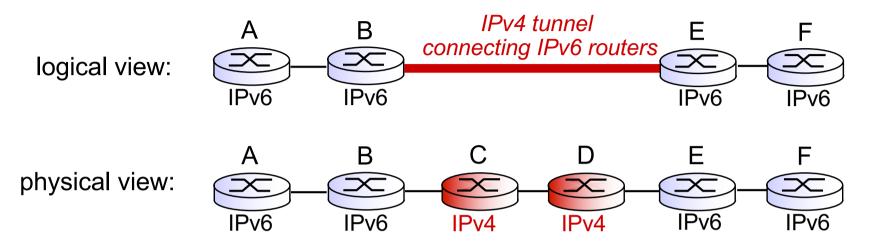

- checksum: removed entirely to reduce processing time at each hop
- options: allowed, but outside of header, indicated by "Next Header" field
- ICMPv6: new version of ICMP
 - additional message types, e.g. "Packet Too Big"
 - multicast group management functions

Transition from IPv4 to IPv6

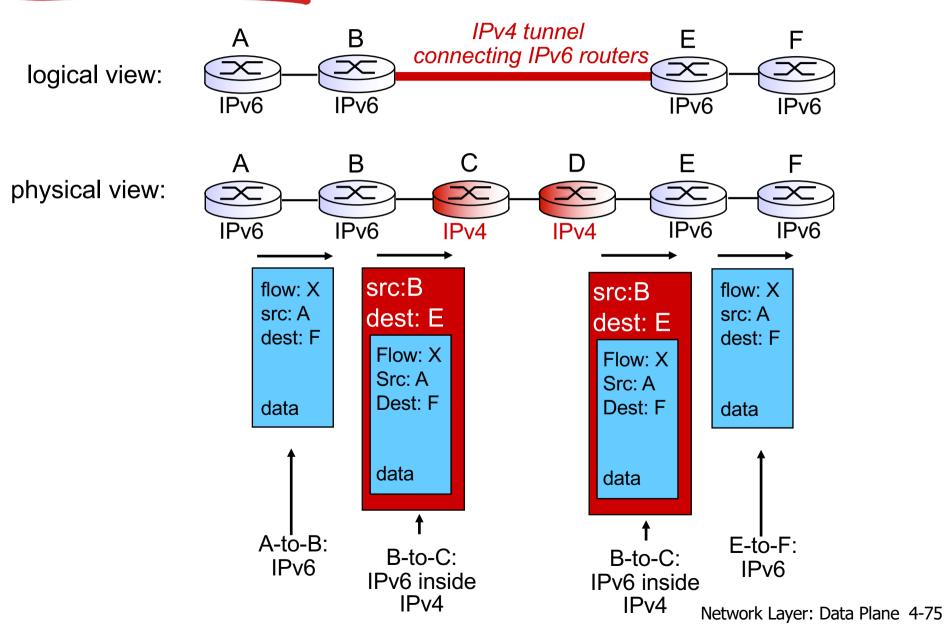

- not all routers can be upgraded simultaneously
 - no "flag days"
 - how will network operate with mixed IPv4 and IPv6 routers?
- tunneling: IPv6 datagram carried as payload in IPv4 datagram among IPv4 routers

Tunneling

Tunneling

- Google: 8% of clients access services via IPv6
- NIST: I/3 of all US government domains are IPv6 capable
- Long (long!) time for deployment, use
 - •20 years and counting!
 - •think of application-level changes in last 20 years: WWW, Facebook, streaming media, Skype, ...
 - •Why?

Chapter 4: outline

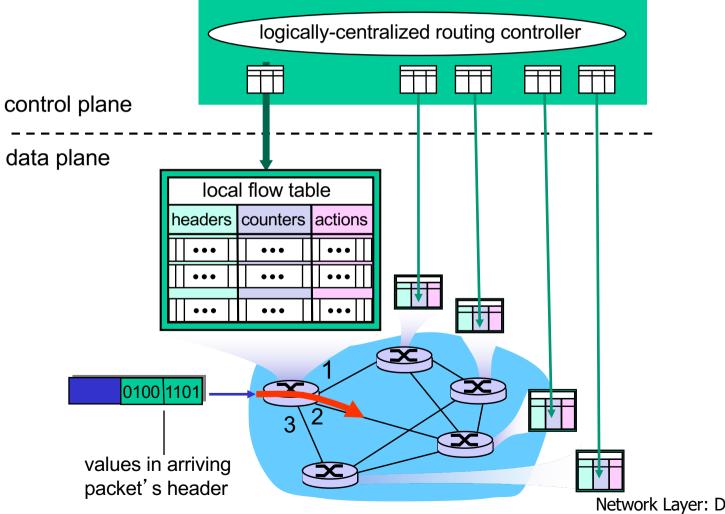

- 4.1 Overview of Network layer
 - data plane
 - control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - network address translation
 - IPv6

4.4 Generalized Forward and SDN

- match
- action
- OpenFlow examples of match-plus-action in action

Generalized Forwarding and SDN

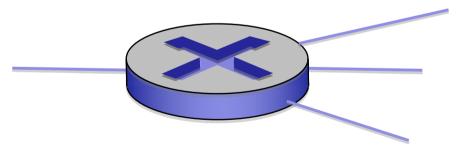

Each router contains a *flow table* that is computed and distributed by a logically centralized routing controller

Network Layer: Data Plane 4-78

OpenFlow data plane abstraction

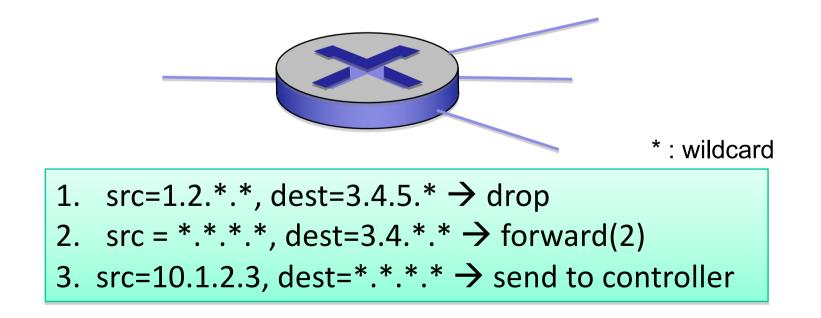

- flow: defined by header fields
- generalized forwarding: simple packet-handling rules
 - *Pattern:* match values in packet header fields
 - Actions for matched packet: drop, forward, modify, or send to controller
 - *Priority*: disambiguate overlapping patterns
 - *Counters:* #bytes and #packets

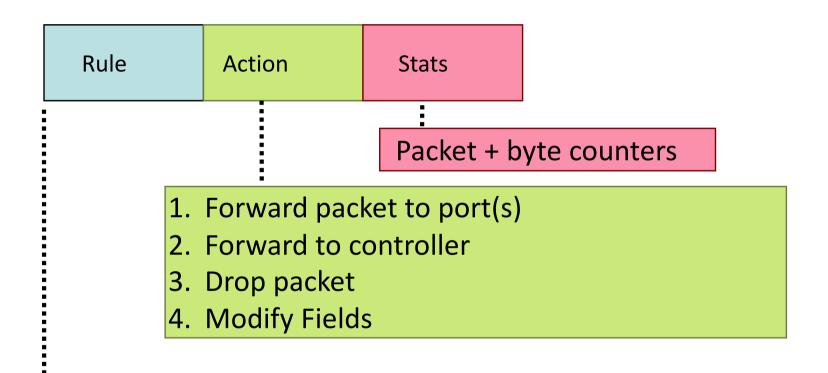

Flow table in a router (computed and distributed by controller) define router's match+action rules

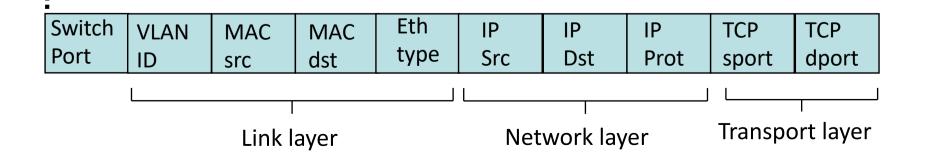

OpenFlow data plane abstraction

- flow: defined by header fields
- generalized forwarding: simple packet-handling rules
 - *Pattern:* match values in packet header fields
 - Actions for matched packet: drop, forward, modify, or send to controller
 - Counters: #bytes and #packets

OpenFlow: Flow Table Entries

Destination-based forwarding:

Switch Port	MA0 src		_			IP Src			TCP sport	TCP dport	Action
*	*	*		*	*	*	51.6.0.8	*	*	*	port6

IP datagrams destined to IP address 51.6.0.8 should be forwarded to router output port 6

Firewall:

Switch Port		C MAC dst	Eth type	VLAN ID	IP Src	IP Dst	IP Prot	TCP sport	TCP dport	Action
*	*	*	*	*	*	*	*	*	22	drop

do not forward (block) all datagrams destined to TCP port 22

Switch Port	MA src	С	MAC dst	Eth type	VLAN ID	IP Src	IP Dst	IP Prot	TCP sport	TCP dport	Action
*	*	*		*	*	128.119.1.1	*	*	*	*	drop
			do	not for	ward (b	olock) a	ll datag	rams s	ent by l	host 12	8.119.1.1

Destination-based layer 2 (switch) forwarding:

Switch Port	MAC src	MAC dst			IP Src	IP Dst	IP Prot	TCP sport	TCP dport	Action
*	22:A7:23: 11:E1:02	*	*	*	*	*	*	*	*	port3
			,		6		~ · · ·	~ ~ ~		

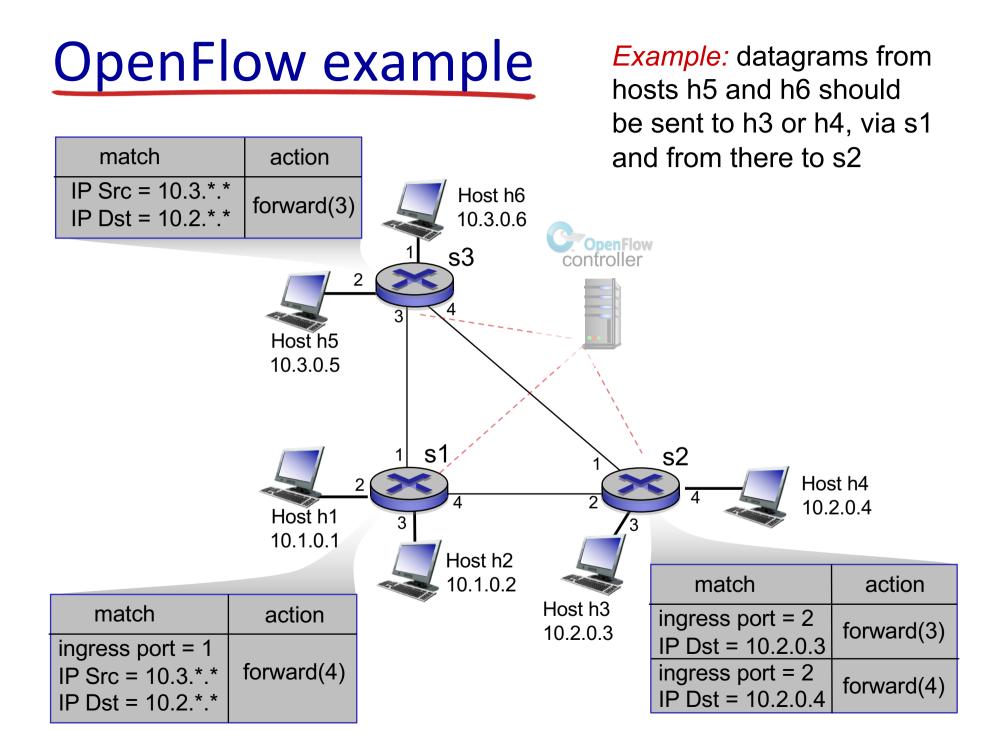

layer 2 frames from MAC address 22:A7:23:11:E1:02

should be forwarded to output port 6

OpenFlow abstraction

- match+action: unifies different kinds of devices
- Router
 - *match:* longest destination IP prefix
 - action: forward out a link
- Switch
 - *match:* destination MAC address
 - action: forward or flood

- Firewall
 - match: IP addresses and TCP/UDP port numbers
 - *action:* permit or deny
- NAT
 - *match:* IP address and port
 - action: rewrite address and port

Chapter 4: done!

- 4.1 Overview of Network layer: data plane and control plane
- 4.2 What's inside a router
- 4.3 IP: Internet Protocol
 - datagram format
 - fragmentation
 - IPv4 addressing
 - NAT
 - IPv6

- 4.4 Generalized Forward and SDN
 - match plus action
 - OpenFlow example

Question: how do forwarding tables (destination-based forwarding) or flow tables (generalized forwarding) computed? Answer: by the control plane (next chapter)
